## Chap 8 - Méthode de point fixe (suite)

Thm 8.3: Soit  $g: \mathbb{R} \rightarrow \mathbb{R}$   $\mathcal{C}^1$ , soit  $\bar{x}$  tq  $g(\bar{x}) = \bar{x}$ , supposons  $|g'(\bar{x})| < 1$ .

Alors  $\exists \varepsilon > 0 \forall \bar{x} - \varepsilon \leq x_0 \leq \bar{x} + \varepsilon$ , la suite déf. par  $x_{n+1} = g(x_n)$

converge vers  $\bar{x}$ . De plus la convergence est linéaire :

$$\exists 0 < C < 1 \forall n \quad |\bar{x} - x_{n+1}| \leq C |\bar{x} - x_n|.$$

Now I state theorem 3.1 from the book. Let  $g$  be a function from  $\mathbb{R}$  to  $\mathbb{R}$ , assumed to be  $\mathcal{C}^1$ , that is once differentiable, and let  $\bar{x}$  be a fixed point of  $g$ , that is  $g(\bar{x}) = \bar{x}$ . Thus it is assumed that there exists a fixed point of this function  $g$ , moreover, it is assumed that the absolute value of  $g'(\bar{x})$  is strictly smaller than 1. The claim is: there exists a positive epsilon such that, if the initial guess  $x_0$  is between  $\bar{x}$  minus epsilon and  $\bar{x}$  plus epsilon, then the sequence defined by  $x_{n+1}$  equal to  $g(x_n)$  converges to  $\bar{x}$ . We have a  $\mathcal{C}^1$  continuous function  $g$ ,  $\bar{x}$  a fixed point of  $g$ , and  $g'(\bar{x})$  in absolute value smaller than 1. In this case, there exists a neighborhood of  $\bar{x}$  such that by choosing  $x_0$  in this neighborhood, insures that the sequence  $x_{n+1}$  equal to  $g(x_n)$  converges to  $\bar{x}$ . There is an extra information: furthermore, the convergence is linear. This means there exists a positive  $C$  strictly smaller than 1, such that for all  $n$ ,  $n$  the iteration index,  $x_{n+1}$  equal to  $g(x_n)$ , for all  $n$ , well the error at step  $n+1$  is smaller or equal to  $C$ , being strictly smaller than one, times the error at step  $n$ . Hence the error decreases at each step, since the ratio between the error at step  $n+1$  and the error at step  $n$ , is strictly smaller than 1.
