Analysis of a Homopolymer

Résumé

We consider the behavior of paths on \mathbb{Z}^d with respect to a Gibb's measure obtained by multiplying the usual measure on simple symmetric random walk paths by

$$\exp \left(b \int_0^t \delta_0(x_s) ds \right)$$

where δ_0 is the Dirac δ at 0, and then normalizing by a factor $Z(t)$ to get a probability measure.

Then the behavior of the resulting paths depends on the dimension and the size of the positive parameter b .

This talk is based on joint work with S. Molchanov.
