Corporate bond liquidity before and after the onset of the subprime crisis

Jens Dick-Nielsen Peter Feldhütter David Lando

Copenhagen Business School

Swissquote Conference, Lausanne October 28-29, 2010

The problem

- Corporate bonds trade at smaller prices i.e. higher promised yield - than similar riskless bonds
- This is because of risk of default (default, loss, risk premium of default risk)
- Liquidity risk or better illiquidity risk also contributes to the spread
- But how do we measure this contribution? Can we disentangle credit and liquidity?

What we show

- The combination of
 - superior data quality of intra-day corporate bond prices using TRACE data
 - natural experiment provided by the onset of the subprime crisis
- help us
 - identifying a set of liquidity proxies which contribute to bond spreads across ratings, across maturity and pre-and post crisis
 - defining an equally weighted average of four standardized liquidity measures which consistently contributes to spreads across time and rating
 - providing new estimates for the liquidity component of corporate bond spreads
 - demonstrating liquidity effects from funding liquidity shocks to lead underwriters
 - defining a liquidity beta for corporate bonds

What we do

- Observe yields and yield spreads quarterly of bonds
- Use detailed TRACE data to compute a collection of liquidity proxies
- Use detailed firm-level information to control for credit risk
- Perform 'marginal' regressions introducing one liquidity at a time controlling for credit
- Extract a principal component of liquidity proxies which is a robust contributor to spreads
- Define an operational measure of liquidity risk
- Compute the contribution in the more liquid segment of corporate bonds to spreads across time, ratings and maturity
- Apply the measure to show the effects of funding shocks to lead underwriters
- Perform robustness checks

Some related papers

Related papers are (among others)

- ► Chen, Lesmond, and Wei (2007), Longstaff, Mithal, and Neis (2005), Huang and Huang (2005), Han and Zhou (2008)
- Goldstein, Hotchkiss, and Sirri (2007), Edwards, Harris, and Piwowar (2007), Bessembinder, Maxwell, and Venkararam (2006), Green, Hollifield and Schürhoff (2007)
- Ericsson and Renault (2006), Bao, Pan, and Wang (2008),
 Acharya and Pedersen (2005)
- ► Houweling, Mentink and Vorst (2005)
- Mahanti, Nashikkar, Subrahmaniam, Chacko, Malik (2008);
 Johnson (2008)

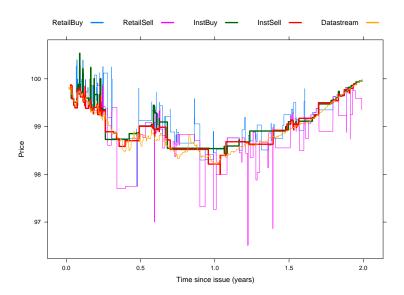

Transaction data from TRACE

- ▶ Transaction data from TRACE for the period (including quarters leading up to) January 1, 2005 - June 30, 2009
- Straight coupon bullet bonds
- ▶ No trades smaller than *USD*100,000
- ▶ Share prices for the issuing firms from CRSP
- Firm accounting figures from Bloomberg

Why we use large trades

- ▶ TRACE allows us to measure volumes of trade
- ▶ Truncate large trades at USD 5 million for investment grade and USD 1 million for speculative grade
- We can see very small trades
- We see a pattern of much larger (implied) bid-ask spreads and very large price differences in intraday trading
- This confirms that factors different from liquidity and credit are at play for small trades
- ▶ We therefore look at trades in excess of USD 100.000

Why we use large trades

Liquidity proxies

Transaction cost measures

- ▶ **Roll measure**: Roll (1984) find that (under certain assumptions) an estimate of the effective bid-ask is $2\sqrt{-cov(\Delta P_i, \Delta P_{i-1})}$
- ▶ Unique roundtrip costs (URC): If there are 2 (investor-dealer-investor) or 3 (investor-dealer-dealer-investor) trades with the same trading volume on a given day, they are (likely) part of a unique roundtrip. URC is the difference between the highest and lowest price (in percentage of price).

An illustration of URC

Liquidity proxies

The Amihud price impact measure

► The Amihud (2002) measure estimates how much a trade of a given size moves prices:

$$Amihud_t = \frac{1}{N_t} \sum_{j=1}^{N_t} \frac{|\frac{P_j - P_{j-1}}{P_{j-1}}|}{Q_j}$$

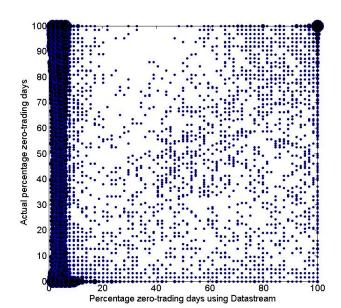

Liquidity proxies

Trading frequency measures

- ► Turnover: quarterly trading volume amount outstanding
- ➤ **Zero-trading days**: The percentage number of days a bond does not trade (Chen, Lesmond, Wei (2007)). We include both **bond** ZTDs and **firm** ZTDs (percentage of days the issuing firm does not have a bond that is trading).

On measuring zero trading days

Datastream vs TRACE

Liquidity proxies

Liquidity risk measures

- ► Investors might require extra compensation for holding assets which are illiquid when asset returns are low
- ➤ This suggests adding a beta to our regressions measuring covariation between illiquidity costs and market returns
- Beta is linear in the standard deviation of illiquidity costs
- We include in our regressions the quarterly standard deviations of the daily Amihud measure and unique roundtrip costs.

Regressions of spreads on single proxies

Control for credit risk

► For each rating class we run separate regressions using quarterly observations

$$\begin{split} \mathsf{Spread}_{it} &= \alpha + \gamma \ \mathsf{Liquidity}_{it} + \beta_1 \ \mathsf{Bond} \ \mathsf{Age}_{it} + \beta_2 \mathsf{Amount} \ \mathsf{Issued}_{it} \\ &+ \beta_3 \ \mathsf{Coupon}_{it} + \beta_4 \mathsf{Time-to-Maturity}_{it} + \beta_5 \ \mathsf{Eq.Vol}_{it} \\ &+ \beta_6 \ \mathsf{Operating}_{it} + \beta_7 \ \mathsf{Leverage} + \beta_8 \ \mathsf{Long} \ \mathsf{Debt}_{it} \\ &+ \beta_{9,pretax} \ \mathsf{Pretax} \ \mathsf{dummies}_{it} + \beta_{10} \mathsf{10} \ \mathsf{y} \ \mathsf{Swap}_t \\ &+ \beta_{11} (\mathsf{10y-2y}) \ \mathsf{Swap}_t + \beta_{12} \mathsf{forecast} \ \mathsf{dispersion}_{it} + \epsilon_{it} \end{split}$$

▶ i is bond issue, t is quarter, and Liquidity_{it} contains one of several liquidity proxies defined below

Which variables matter in marginal regressions?

- Significant in most rating categories pre and post crisis:
 - Amihud measure
 - Amihud measure risk
 - Roundtrip costs (URC)
 - ▶ URC risk
- ▶ The signs are consistent for these proxies
- Significance of other measures is more scattered, and signs vary

Principal component analysis of liquidity proxies

- ► Given the high level of correlation between our main measures, we choose to extract principal components
- The measures are of course on very different scales, so we extract PCs from the correlation matrix
- Principal component analysis reveals that PC1 loads mainly on the four measures
- This is true pre and post crisis and weights for the four are almost identical
- ▶ PC2 is related to zero trading days, PC3 is mainly turnover

Principal component loadings - before crisis

Our liquidity measure

- ▶ The loadings on the PC1 are very close to equal
- ▶ The significance of PC1 is robust
- We simply define a liquidity measure which is the equally weighted combination of these measures
- ▶ I.e. Let \mathcal{L}_{it}^{j} denote the type j liquidity measure of bond i in quarter t
- ▶ j is an index for the Amihud measure, Amihud measure risk, URC and URC risk
- Normalize by the mean and standard deviation of measure j across bonds and quarters, i.e. let $\tilde{L}^j_{it} = \frac{L^j_{it} \mu^j}{\sigma^j}$
- ▶ Define $\lambda_{it} = \sum_{j=1}^{4} \tilde{L}_{it}^{j}$
- ▶ We do the computations separately for the two regimes

Contribution to spreads from liquidity

- ightharpoonup Call our measure λ
- Let λ_{it} denote the value of the liquidity measure for bond i at date t
- Perform the regression for each rating class

$$spread_{it}^R = \alpha^R + \beta^R \lambda_{it} + credit risk controls_{it} + \epsilon_{it}$$

- Group bonds according to maturity also
- ▶ Within each category (rating, maturity), sort λ_{it} according to size
- ▶ Define 5% and 50% quantiles λ_5, λ_{50}
- Report $\beta^R(\lambda_{50} \lambda_5)$
- Bootstrap standard errors

Liquidity spread:

Difference between median and high liquidity level

Contribution to spreads from liquidity - robustness

- We also try with higher liquidity measure
- ▶ Define 5% and 75% quantiles λ_5, λ_{75}
- ▶ Report $\beta^R(\lambda_{75} \lambda_5)$
- We try with swap rates instead of treasuries as benchmark riskless rate
- ► We perform matched regressions using pairs of bonds from same issuer with close to equal maturity
- Idea is that credit risk controls can now be replaced by a pair specific dummy variable

The maturity structure

- ▶ We also try to group by rating only (across maturities)
- ...and by maturity only (across ratings)

Maturity effects

Dynamic of key variables

- ▶ Note distinct patterns in increase in our four variables
- Remarkable fact: Lower turnover but also fewer bond zero days after onset
- ▶ This can be explained by smaller trade sizes

Dynamics of liquidity proxies

On trading volume and size

Liquidity betas

- Introduction of 'liquidity betas' as regressors measuring the extent to which the individual bond's liquidity varies with overall bond market liquidity
- We obtain bond-specific betas by regressing the bond specific measure λ_i (in quarters where it can be computed) on the average (weighted by amount outstanding) of all bond specific measures
- ▶ We have to use the entire sample period 2004Q4-2009Q2 to obtain these estimates, since subdividing into two periods gives noisy estimates
- We find that before the crisis, this beta does not contribute to spreads (except for AAA)
- After the crisis, the picture is the opposite and there is a contribution except for AAA
- Consistent with flight-to-quality

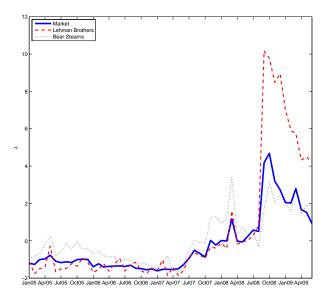

The effect of liquidity betas

Funding liquidity affects market liquidity

- Lead underwriters typically maintain a market-maker role in secondary market
- ► Funding liquidity of market-maker may affect ability to provide liquidity (see for example Brunnemeier and Pedersen (2009))
- ► We can compare corporate bonds underwritten by distressed firms with the overall sample and we find a clear effect of stress to funding liquidity

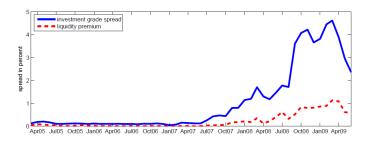

The effect of lead underwriter

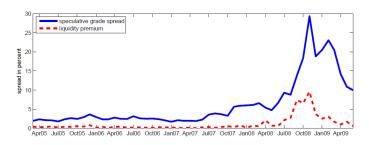

Liquidity contribution over time

- ► We can also use our measure to look at the liquidity contribution to spreads over time
- ▶ We show result for investment grade and speculative grade
- Overall conclusion is that the illiquidity premium has returned to pre-crisis level in the speculative grade segment, but remains higher in the investment-grade segment

Decomposition over time

Summary of main points

- TRACE data and onset of crisis provide new insights into liquidity proxies
- ▶ Based on a principal component analysis we propose a simple equally weighted average of four liquidity measures
- ► This measure consistently (across ratings, in different regimes) is a significant determinant of credit spreads in corporate bonds
- ► Larger liquidity components after the onset of the crisis (both in levels of component and in regression coefficient response)
- Premiums seem to have returned to pre-crisis levels for speculative grade but remain higher for investment-grade
- ► Higher components for lower credit quality, and mostly increasing with maturity
- ► Confirm effect of funding liquidity on market liquidity

Supplementary tables

Liquidity spread:

Difference between low (75% quantile) and high liquidity level

Panel A: Liquidity component in basis points, pre-subprime

(2004Q4-2007:Q1)							
	average	0-2y	2-5y	5-30y	N 0-2y	N 2-5y	N 5-30y
AAA	1.4	1.0 (0.5;1.3)	1.2 (0.7;1.7)	2.0 (1.1;2.8)	162	178	193

Matched regression

- What if we have not measured credit risk correctly?
- We pair bonds from the same firm with similar maturity
- We insist that they have the same regression coefficient on the liquidity variable but introduce a constant dummy for each bond
- ▶ This will capture any credit risk misspecification
- ▶ Due to reduction in data set, we perform this in larger buckets: investment grade and speculative grade
- $ightharpoonup \lambda$ again consistently significant
- ► We also perform Durbin-Wu-Hausman test for endogeneity using bond age as instrument

Robustness control for credit
