

# Two examples of granular materials “engineered” for strength: Granular crystals, entangled matter

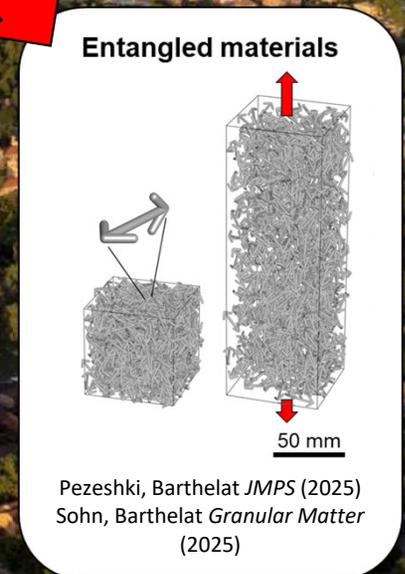

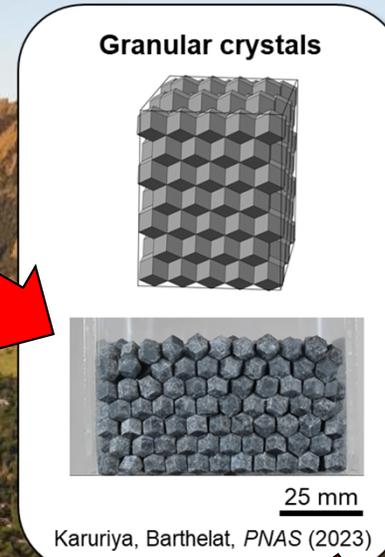

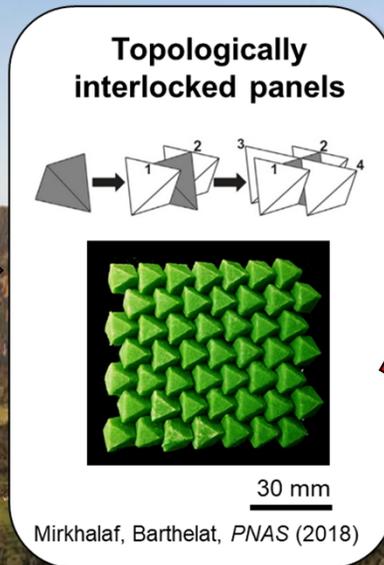

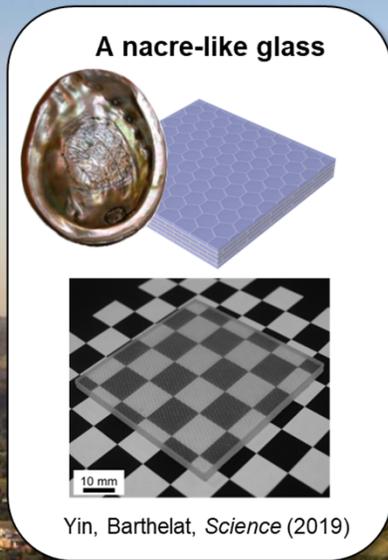

**Francois Barthelat**

Laboratory for Advanced Materials and Bioinspiration

Department of Mechanical Engineering, University of Colorado Boulder

*IIC Distinguished Lectures seminar, EPFL 05/21/2025*

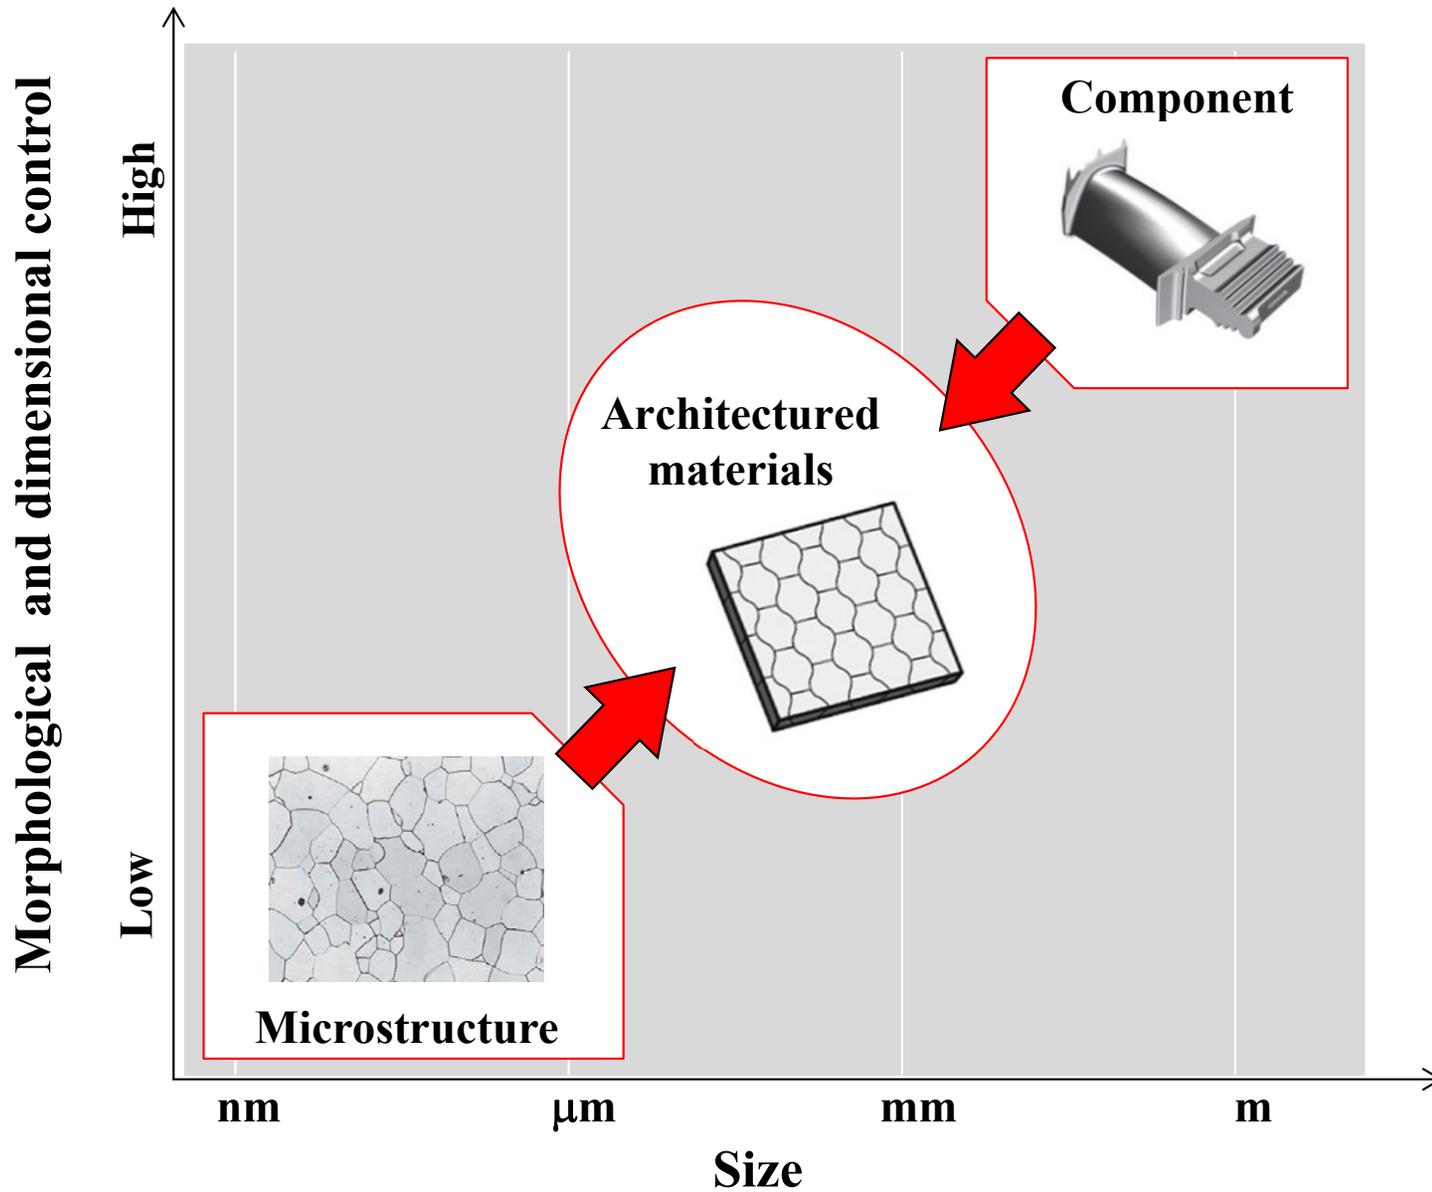

# Our approach to materials design...

## **General design recipe:**

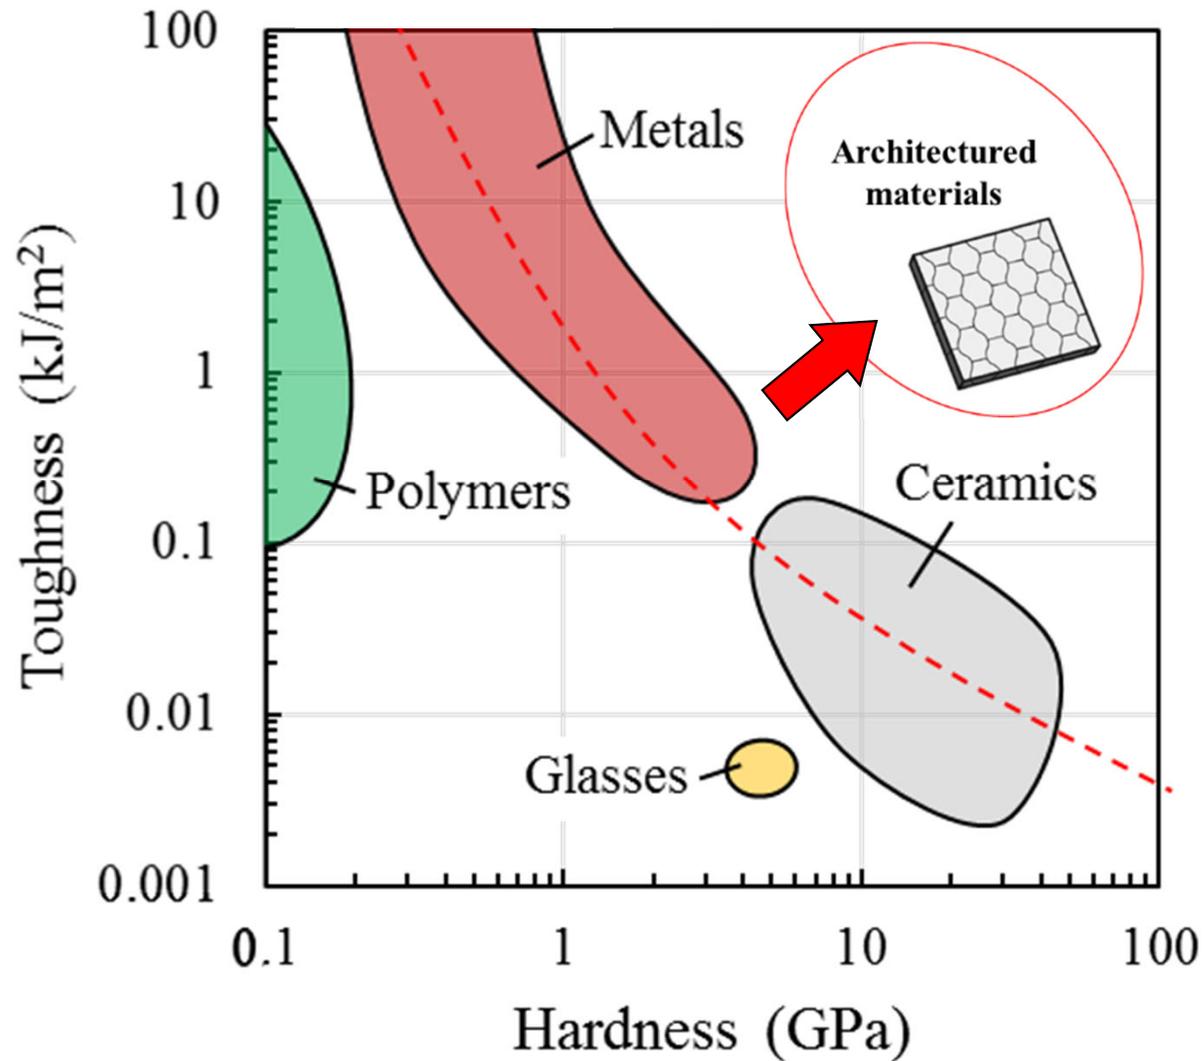

- **Stiff, millimeter size, identical “building blocks”**
- **Material architecture**
- **Weaker interfaces**
- **Geometric hardening, interlocking**

# Material architecture

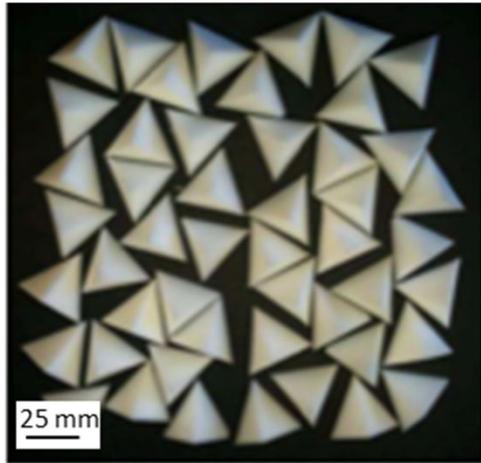

Adapted from Brechet & Embury Scripta Materialia 68 (2013)  
F. Barthelat, International Materials Reviews 60(8) (2015)

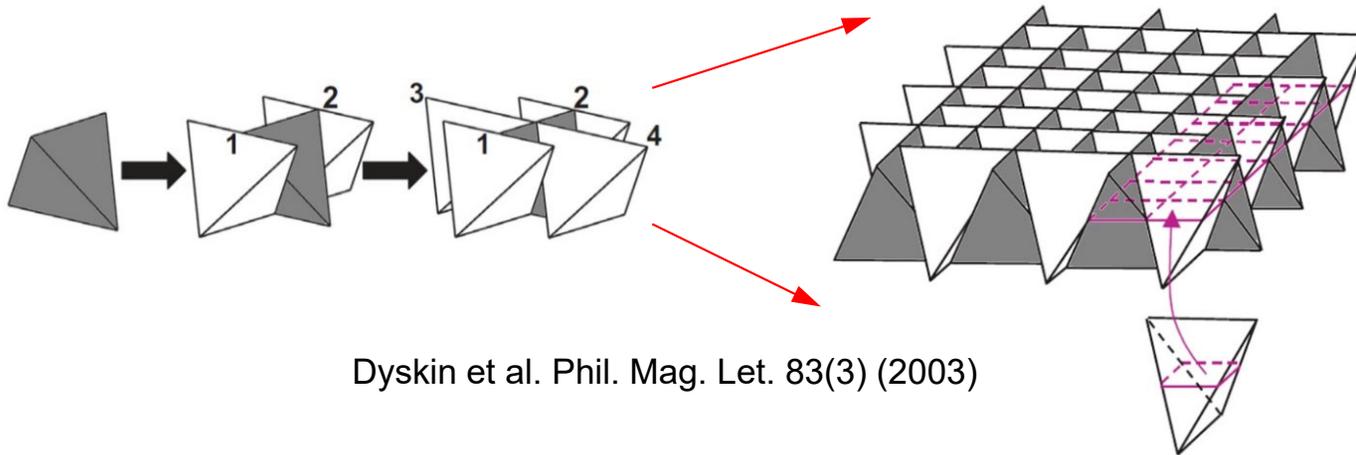

# Architected materials for strength and toughness

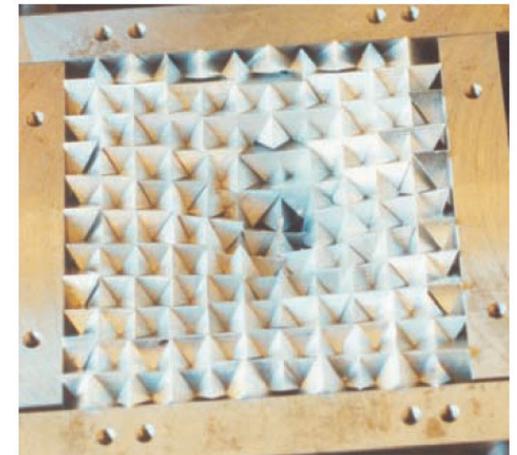

# Topologically interlocked materials (TIMs)

- Interlocked tetrahedral blocks
- No physical joining
- Individual blocks remain elastic, but can slide on one another: large inelastic deformations are possible at the macroscale
- Toughness is gained, but generally at the expense of strength

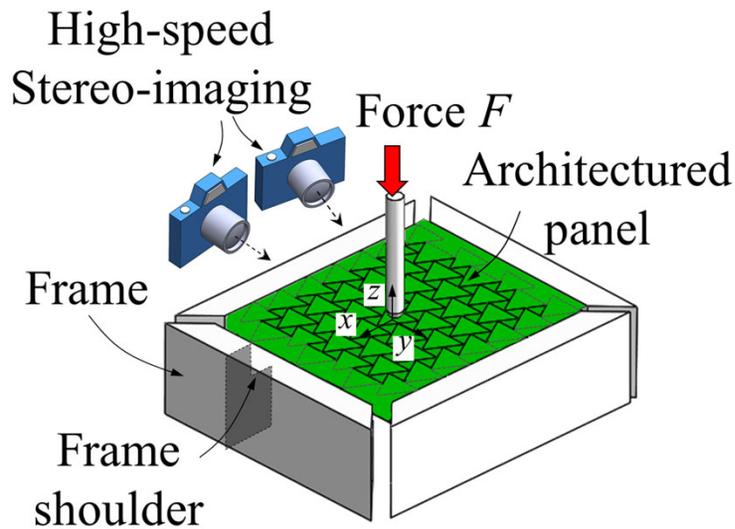

Dyskin et al. Phil. Mag. Let. 83(3) (2003)

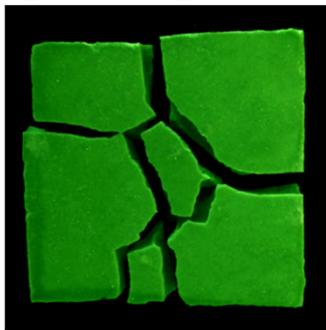

S. Khandelwal and T. Siegmund  
Int. J. Solids Struct. 49 (2012)

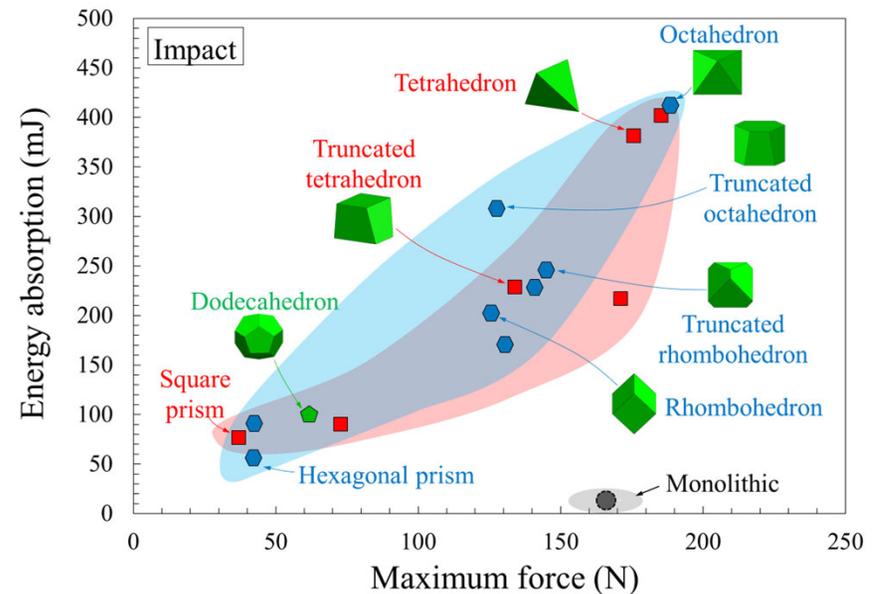

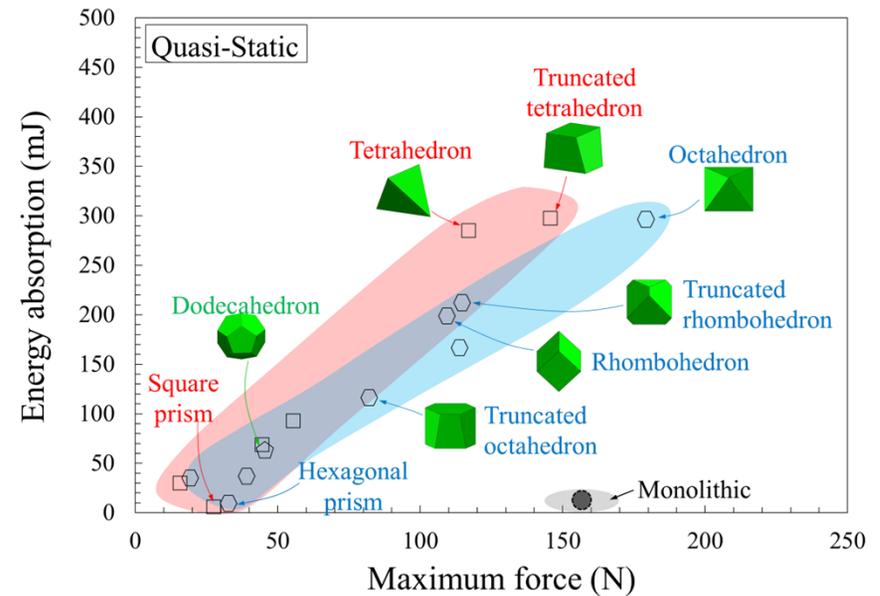

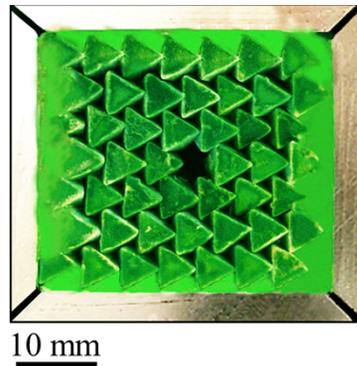

# Experiments

Monolithic plaster panel

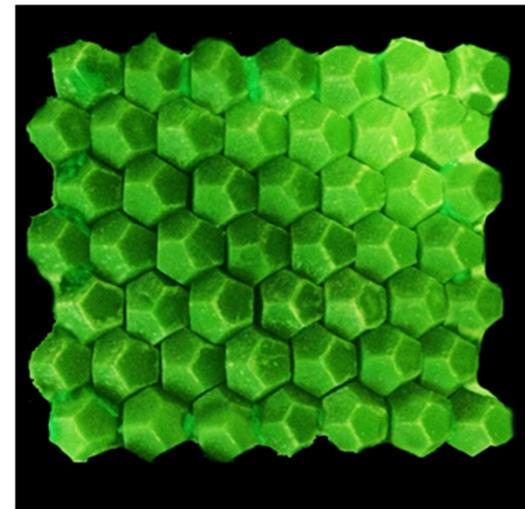

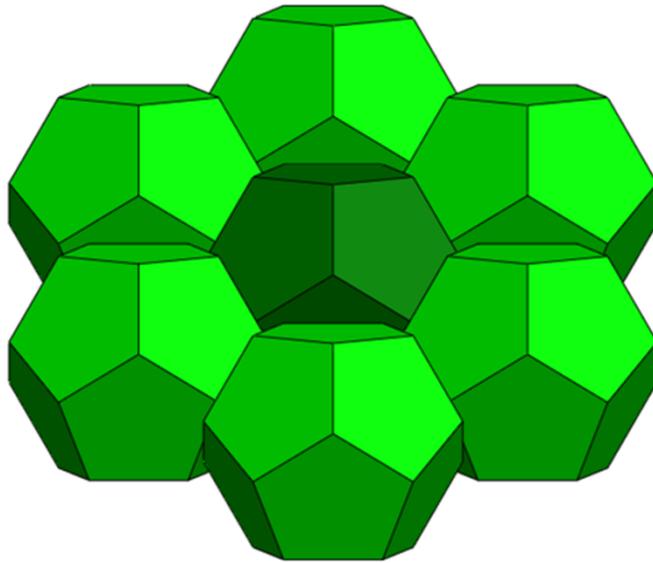

Architected plaster panel

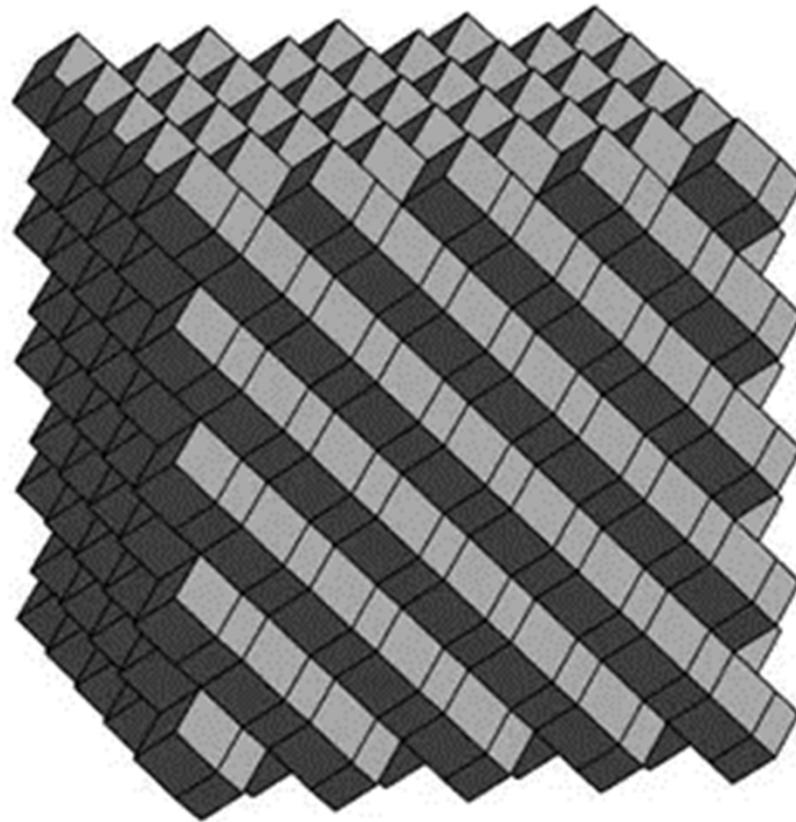

**Octahedral blocks provide the highest performance: 50 times improvement in impact resistance, 20% improvement in strength**

# Are topologically interlocked panels $2D$ *granular crystals*?

30 mm

# Expand these concepts to 3D materials?

# Mechanics of sand and other typical granular materials

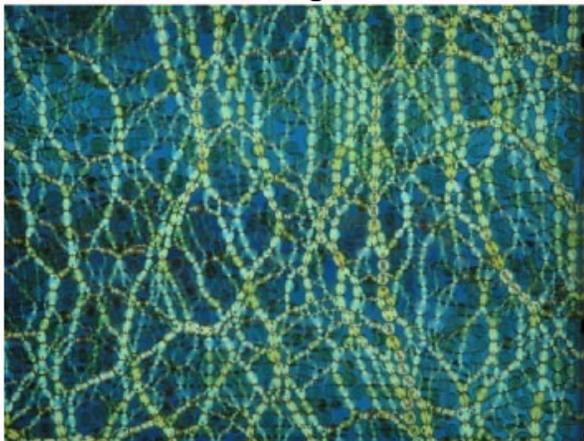

Confined sand, jammed and in “solid state”

Unconfined sand in “liquid state”

- Sand – and granular materials in general – are fascinating materials that can behave like solid or liquids
- Traditional granular materials make poor structural materials: poor packing, suboptimal load transfer and randomness limit design possibilities, performance and advanced functionalities

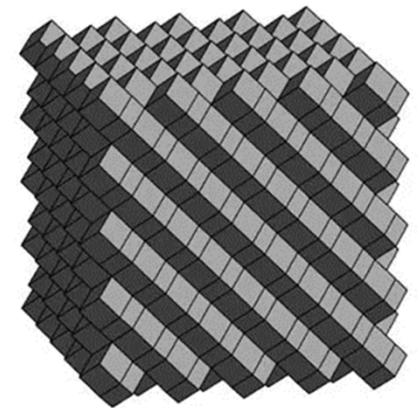

Load transfer in typical granular materials is localized along thin force lines

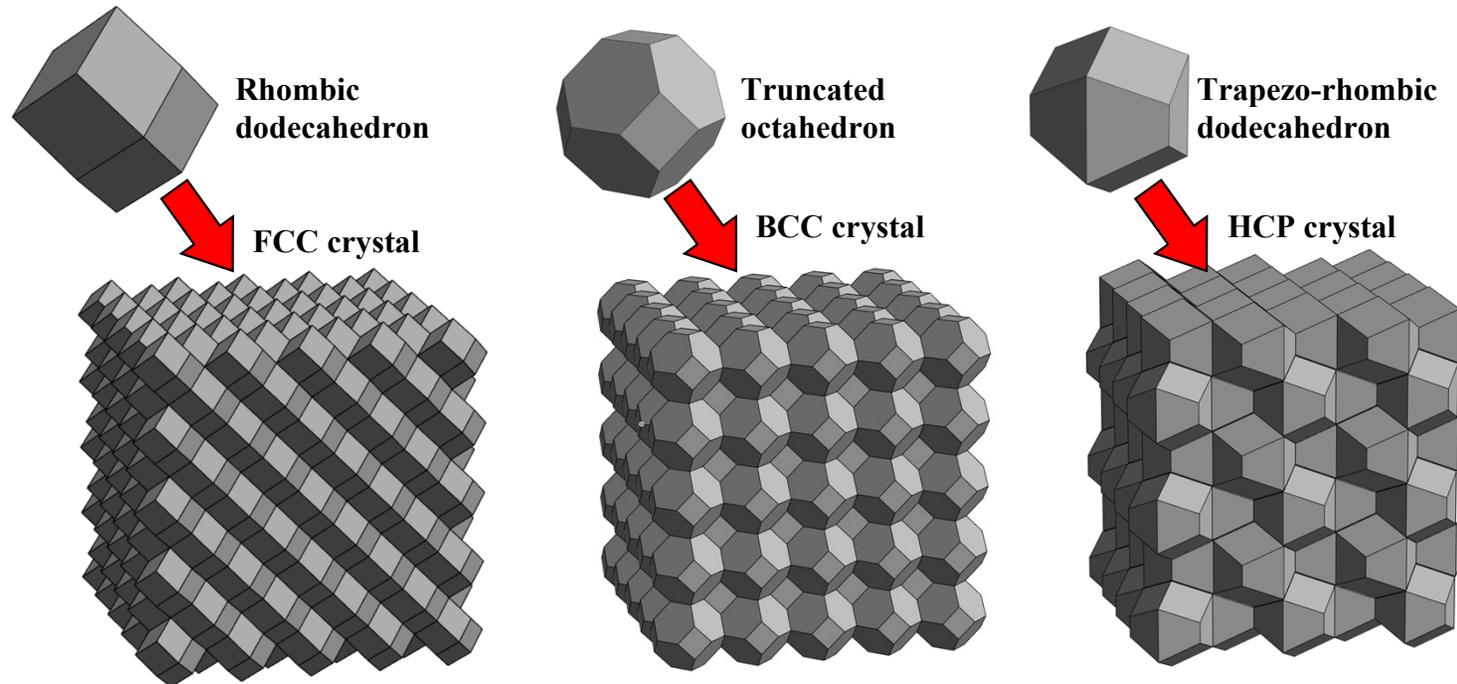

Behringer, Rep. Prog. Phys. 82, 012601 (2018)

*Can we design the shape of the grains, their arrangement and their interfaces to improve mechanical performance?*

# Fully dense granular crystals?

## ***Key Advantages***

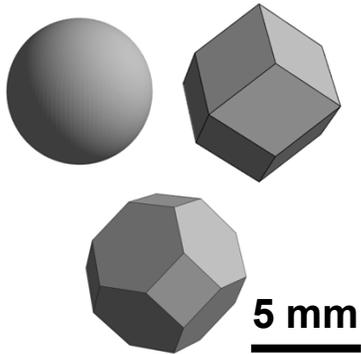

- **Optimized flat-on-flat contact mechanics**
- **Dense network of ordered force lines**
- **High stiffness and strength**
- **Mechanics and properties can be manipulated over multiple length scales**

20 mm

# Fine tuning the experimental protocol

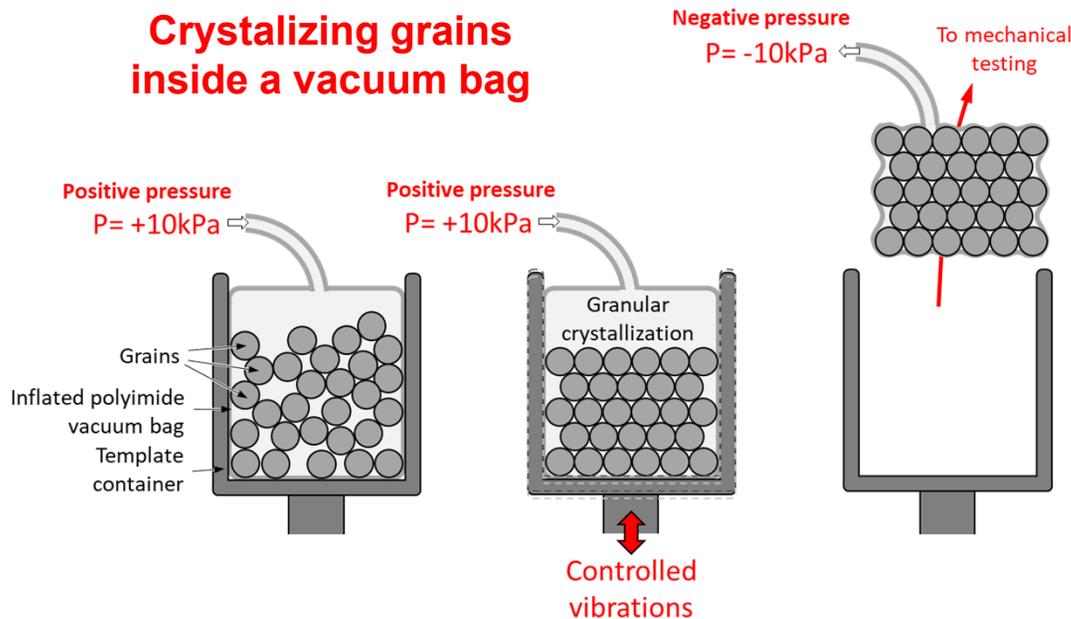

Volume of individual grains kept constant across all geometries ( $132 \text{ mm}^3$ )

Number of grains ( $N=800$ ) and sample geometry identical for all samples

Crystallizing grains inside a vacuum bag

N. Karuriya and F. Barthelat "Granular crystals as strong and fully dense architected materials" *PNAS* 120(1) (2023)

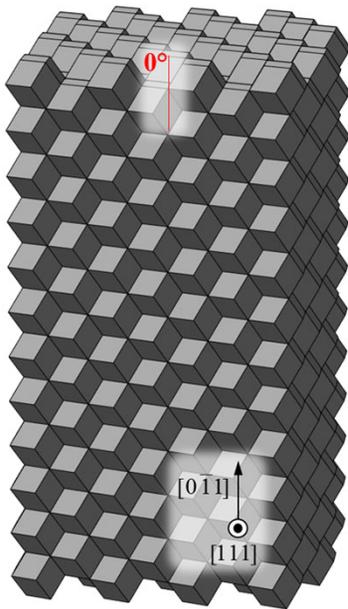

# Crystallographic orientations

**Vibration box as template for crystallization:**

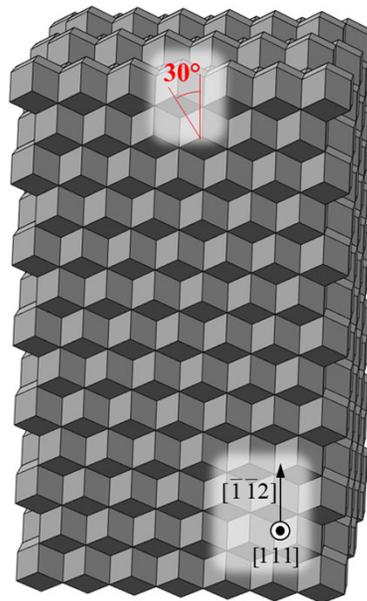

- Planes of densest packing are templated by the flat floor of the box
- Rows of densest packing are templated by long walls of the box (on-axis samples), or by the short walls (in off-axis samples).

**FCC Crystal of Rhombic Dodecahedra (CRD)**

**On-axis (0°)**

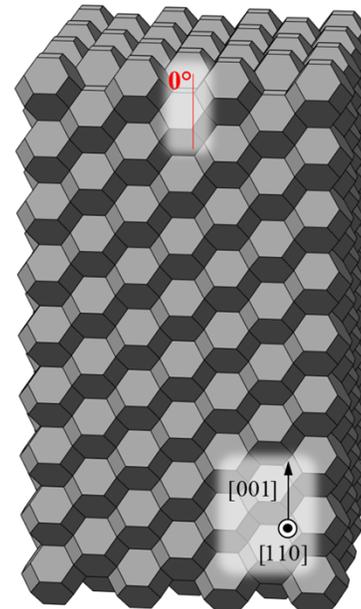

**Off-axis (30°)**

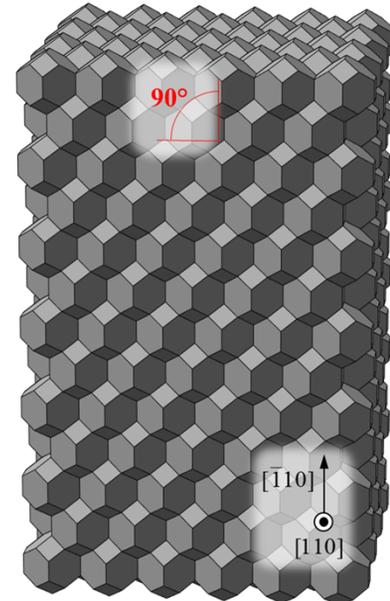

**BCC Crystal of Truncated Octahedra (CTO)**

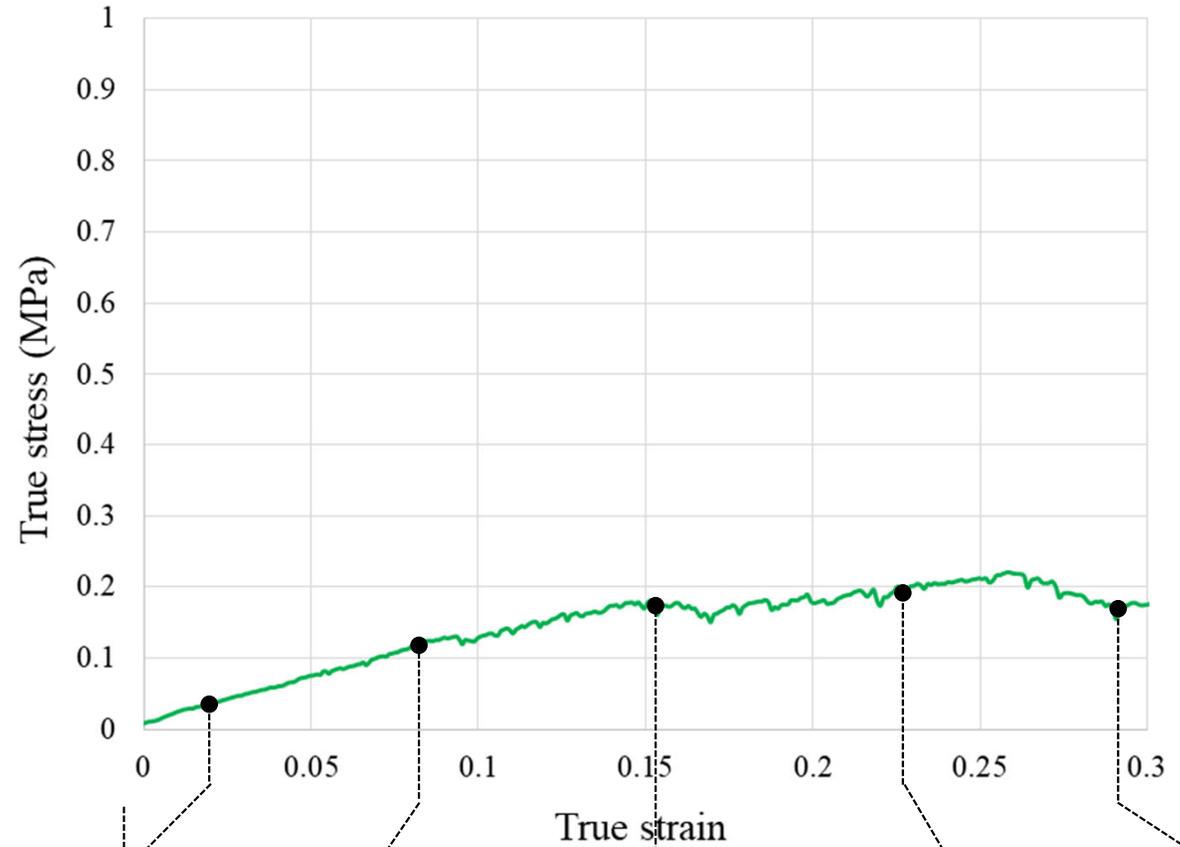

**On-axis (0°)**

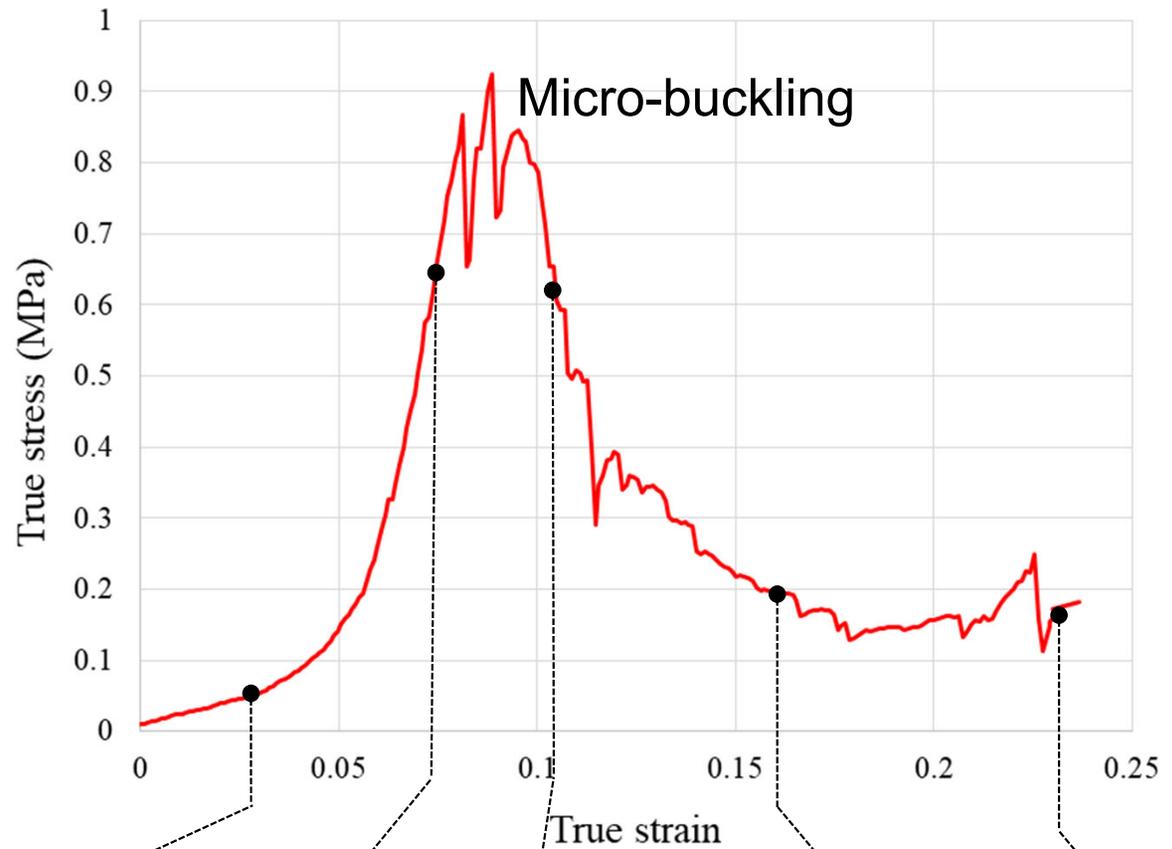

**Off-axis (90°)**

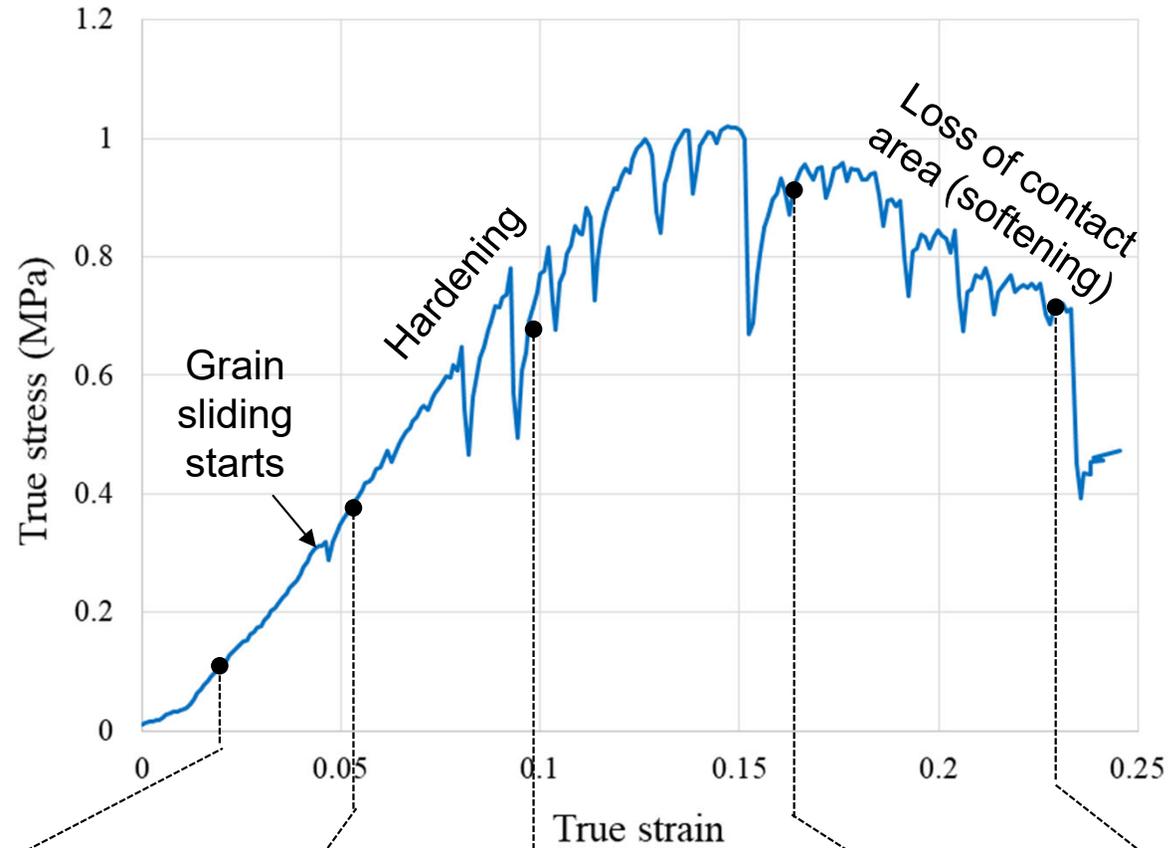

# Randomly packed grains

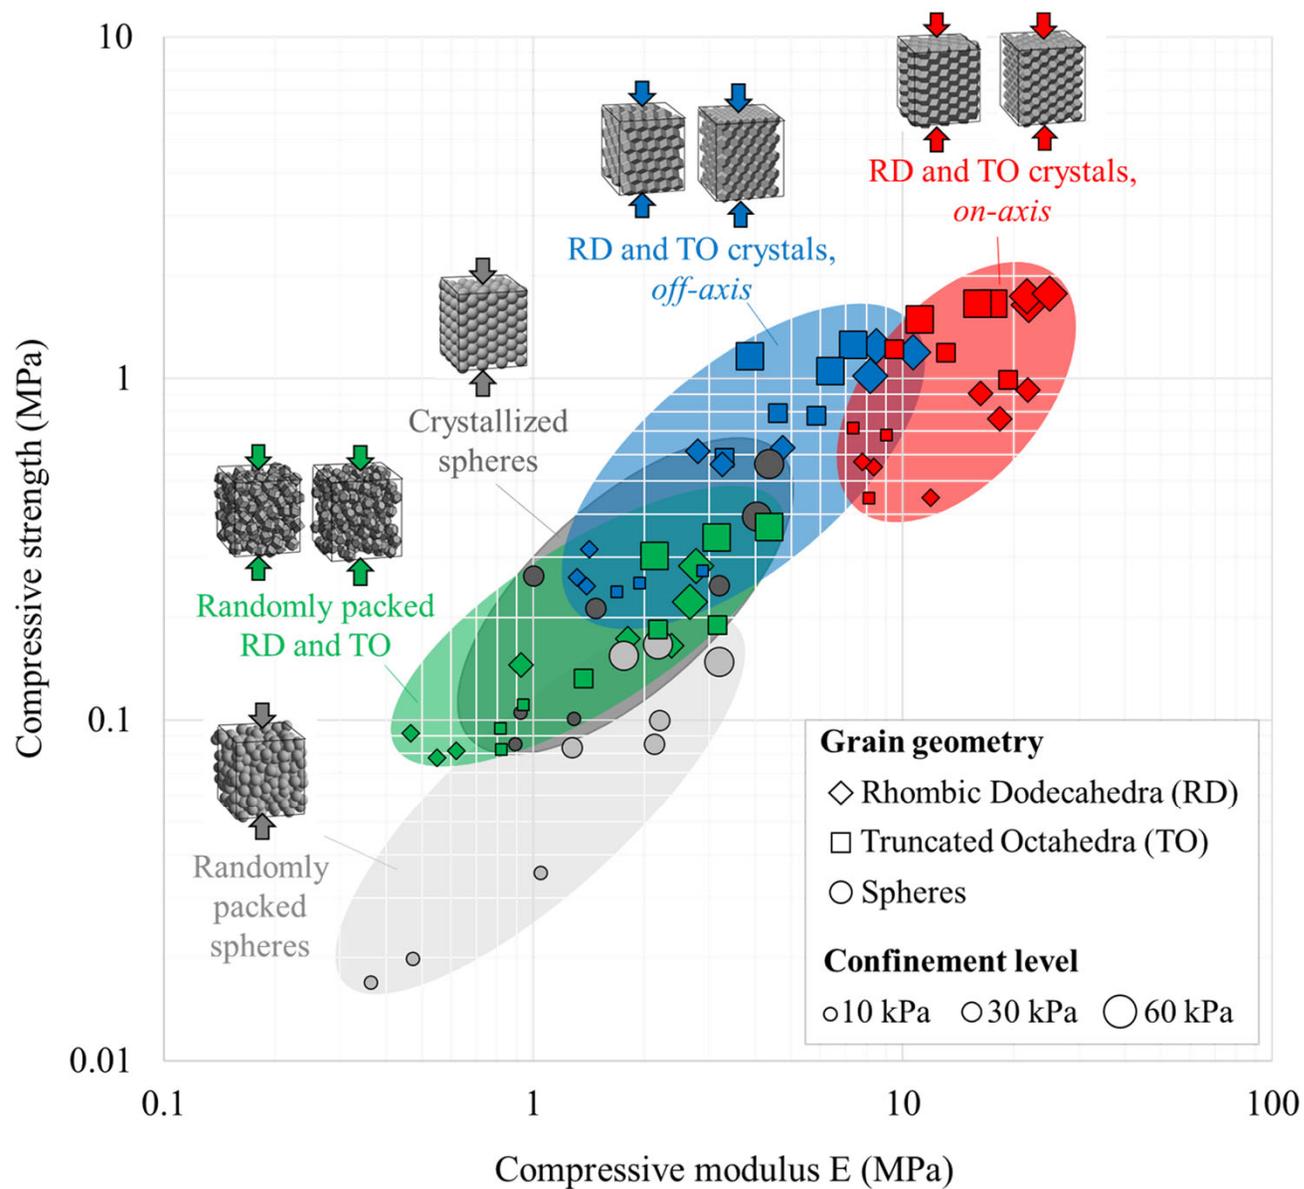

# On-axis FCC crystals

# Off-axis FCC crystals

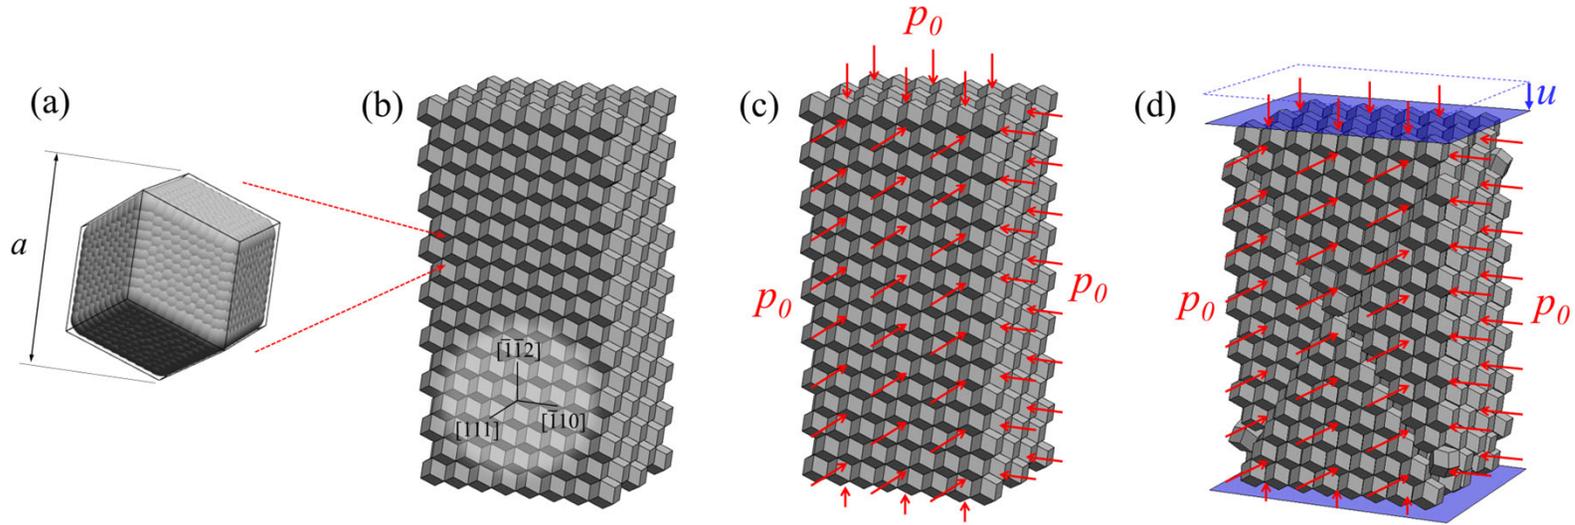

- **Strong correlation between strength and modulus**
- **Crystallized spheres are 2 to 4 times stronger than randomly packed spheres (same stiffness)**
- **RD and TO based granular crystals are 3 to 7 times stronger than their randomly packed counterparts**
- **Dense granular crystals are up to 25 times stronger than regular granular materials**

N. Karuriya and F. Barthelat "Granular crystals as strong and fully dense architected materials" *PNAS* 120(1) (2023)

# Discrete Element Models (DEM)

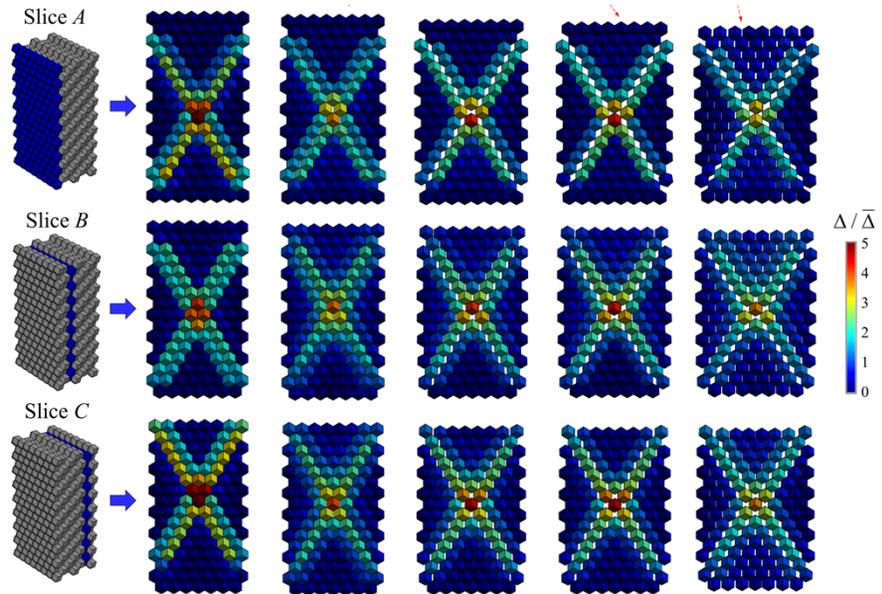

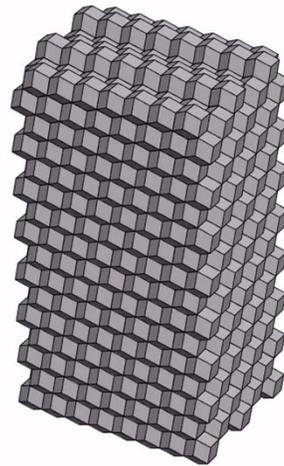

## Overlapping spheres DEM model with LAMMPS

Experiment

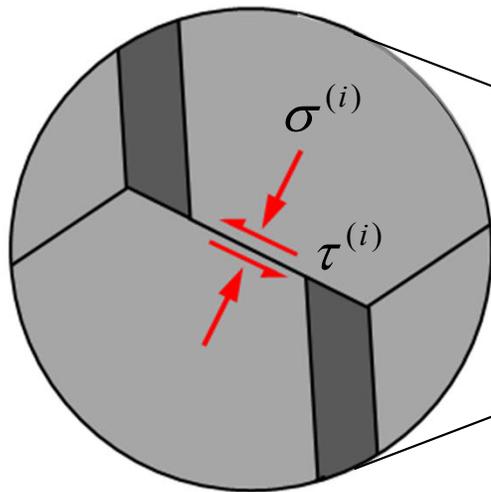

DEM model

A.N.Karuriya and F. Barthelat, "Plastic deformations and strain hardening in fully dense granular crystals" (JMPS 186, 105597, 2024)

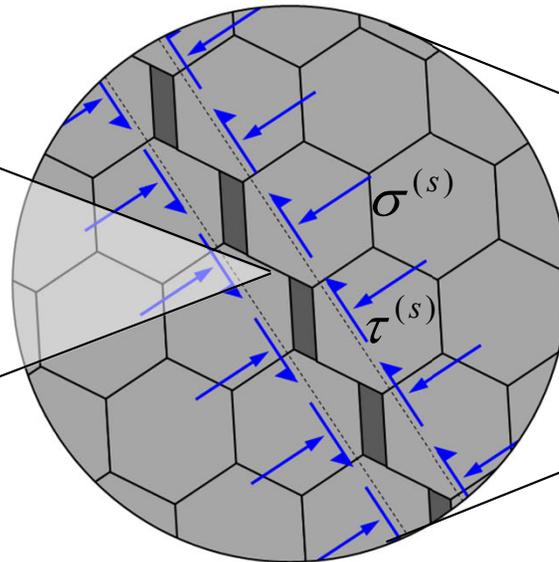

# A “Granular crystal plasticity” model

**Level 1:  
Grain-grain friction**

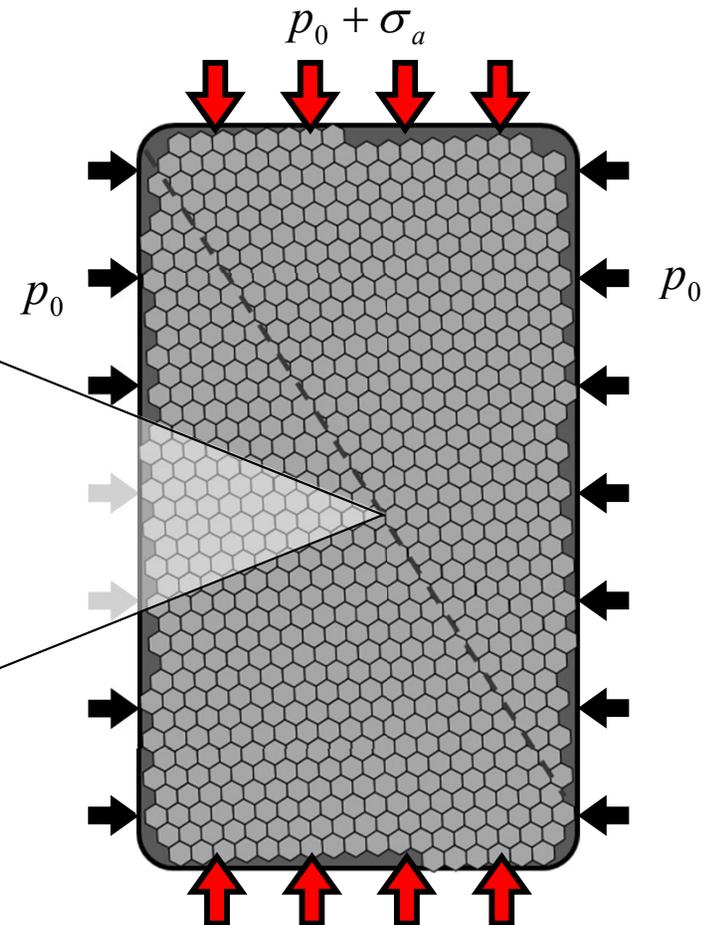

$$\frac{\tau^{(i)}}{\sigma^{(i)}} = f^{(g)}$$

**Level 2:  
Slip plane**

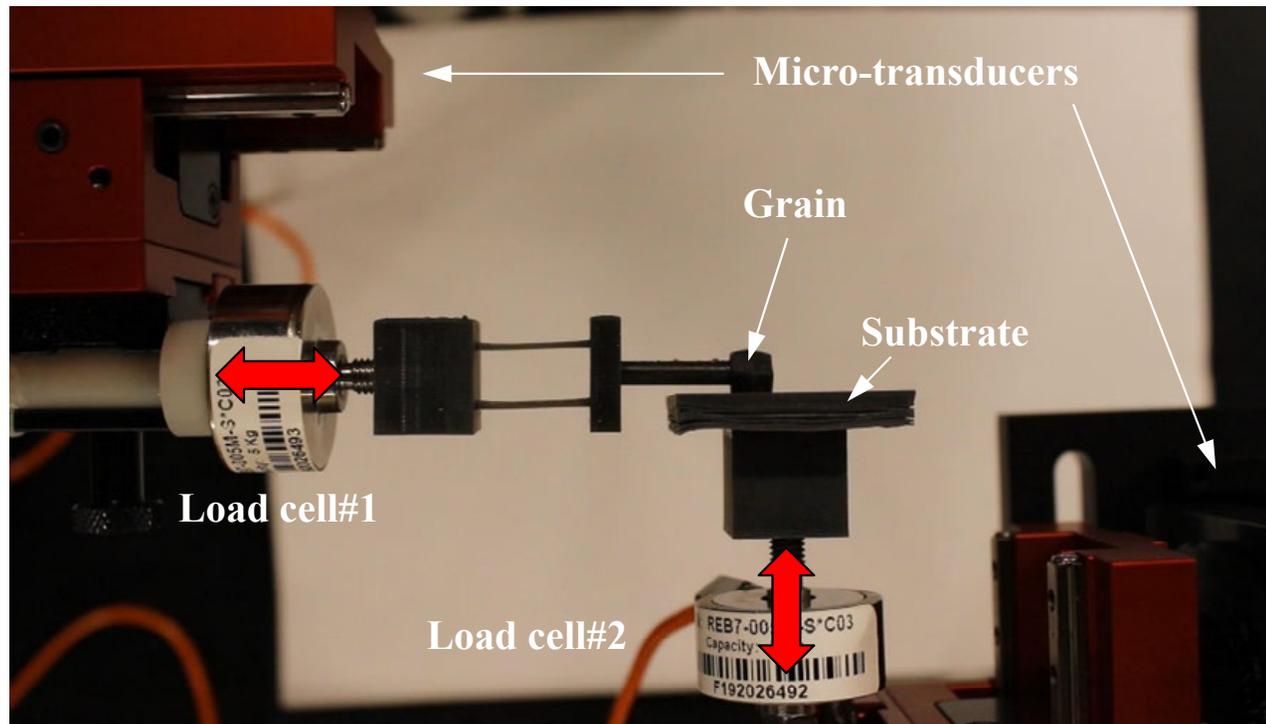

$$\frac{\tau^{(s)}}{\sigma^{(s)}} = f^{(s)}$$

**Level 3:  
Triaxial compression**

$$\text{Compressive strength} = \frac{\sigma_y}{p_0}$$

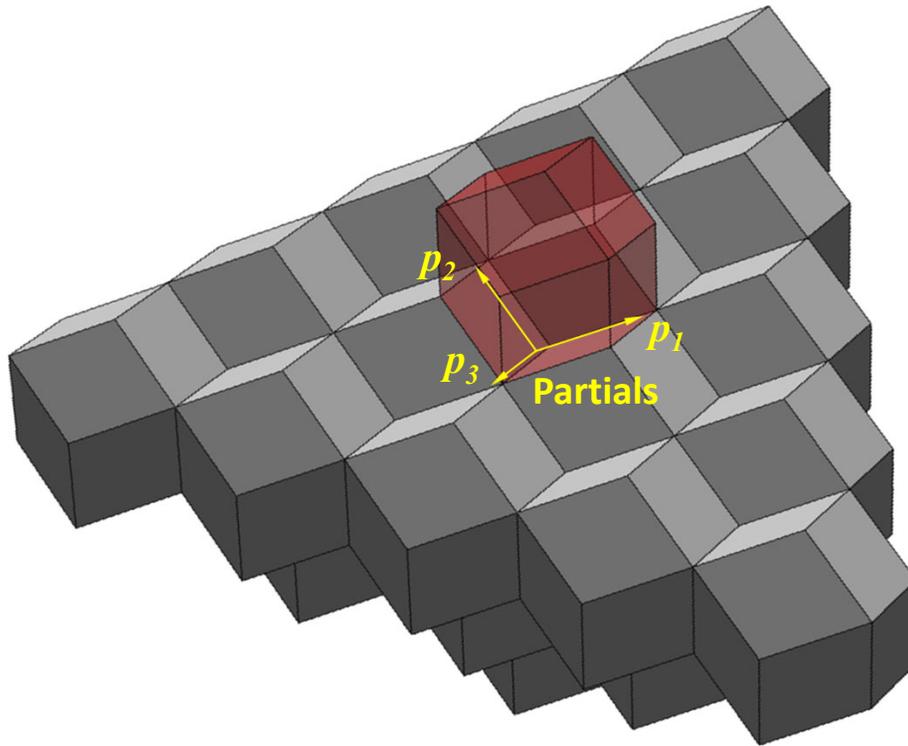

# Level 1: Grain-on-grain friction

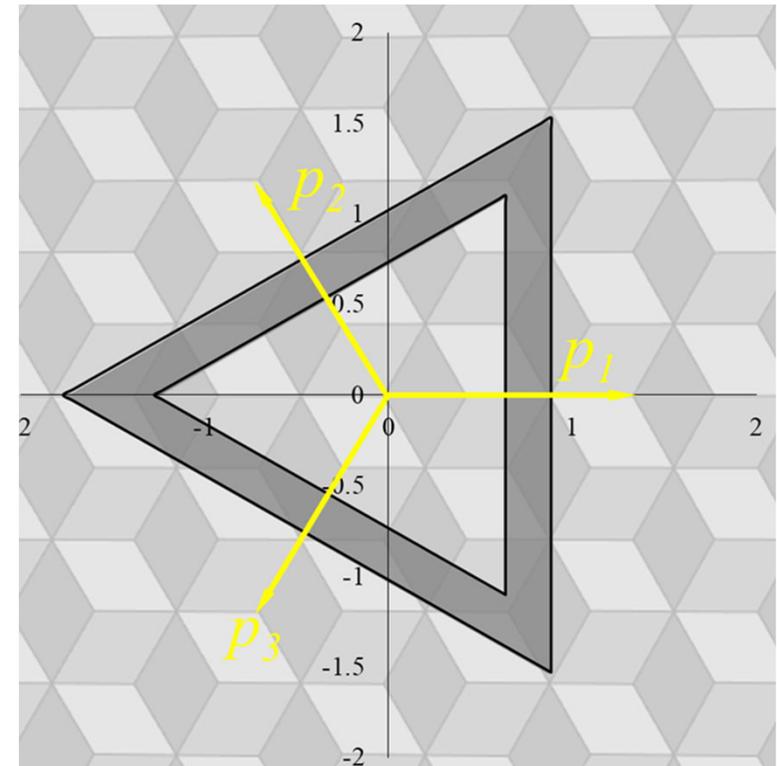

Measured coefficient of friction:  $f^{(g)} = 0.30 \pm 0.05$

# Level 2: Slip plane friction

Frictional grain motion over a (111) slip plane in FCC crystal

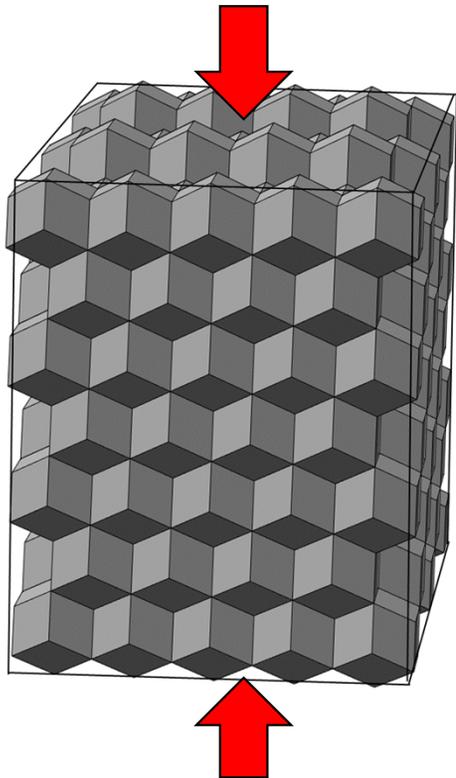

Range for friction coefficient of (111) slip plane with grain-to-grain friction  $0.25 < f^{(g)} < 0.35$

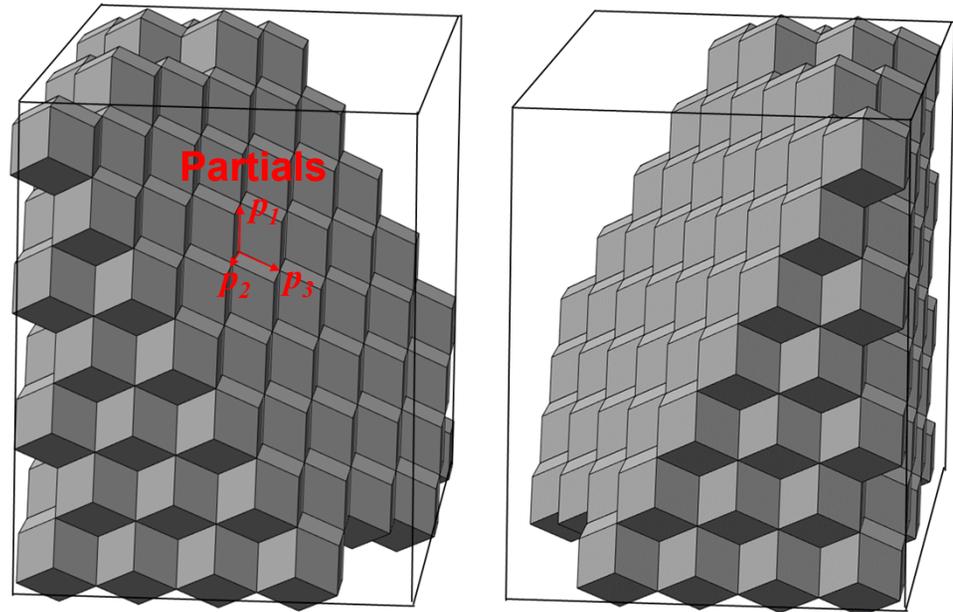

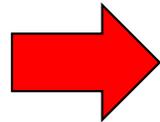

# Level 3: Granular crystal plasticity

Off-axis loading direction

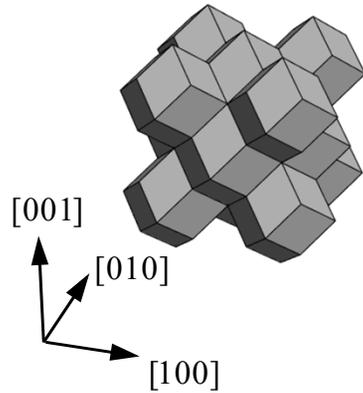

Example showing an activated (111) plane

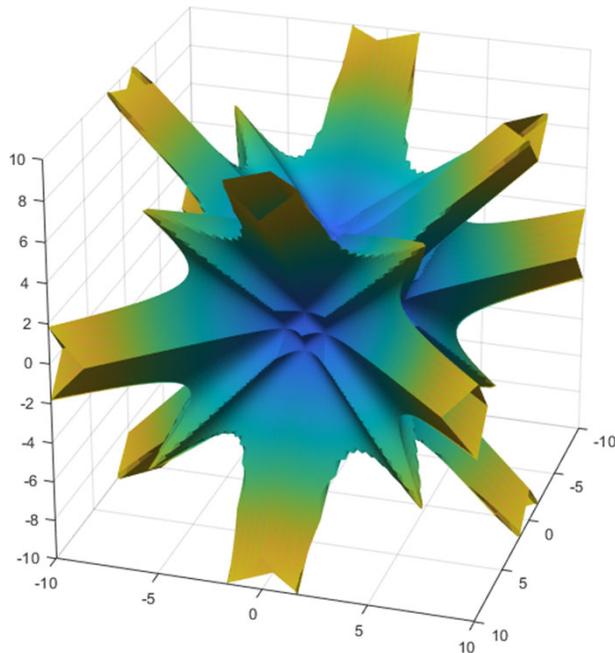

# Plasticity in FCC granular crystal

FCC crystal of dodecahedra

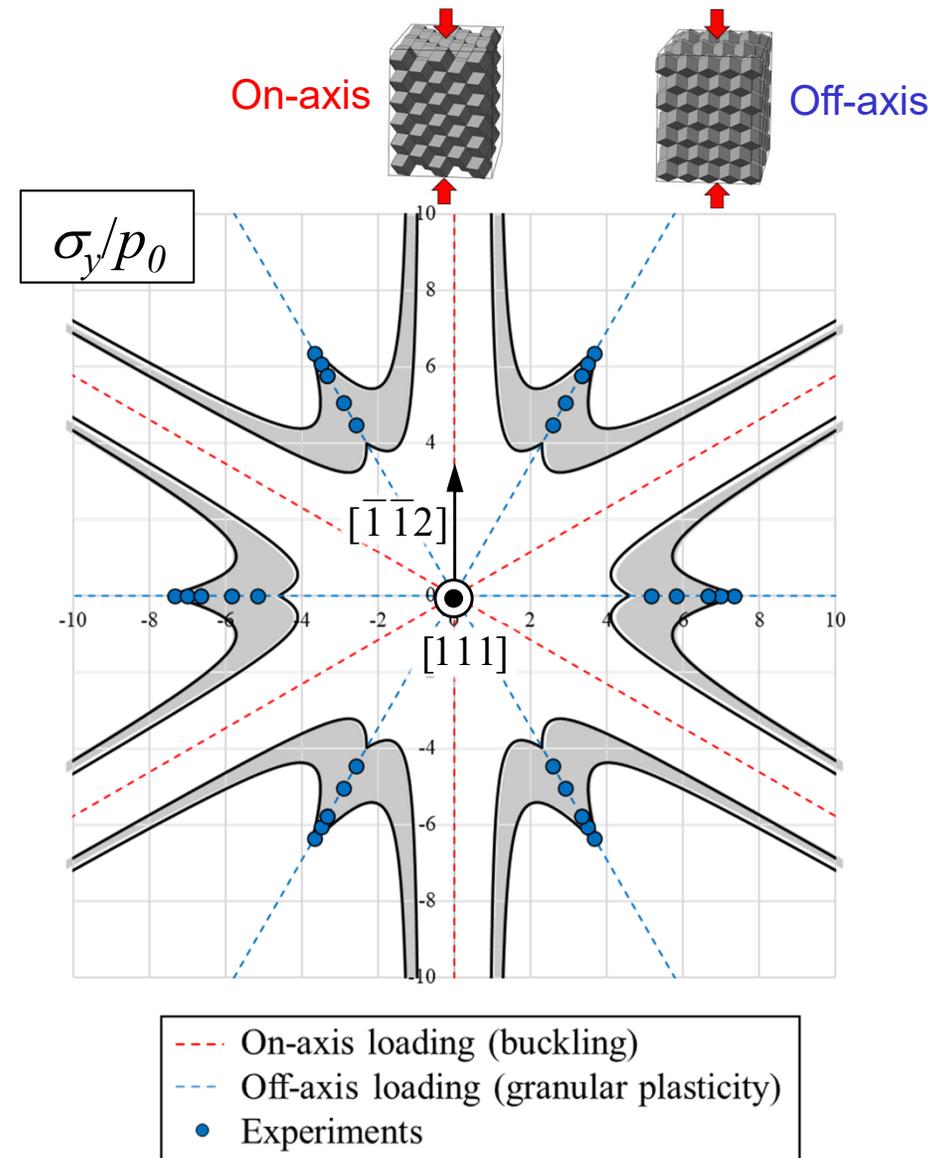

Anisotropic yield strength  $\sigma_y/p_0$

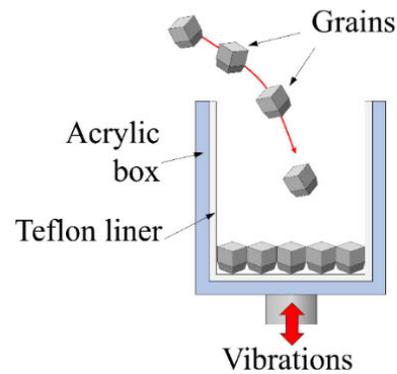

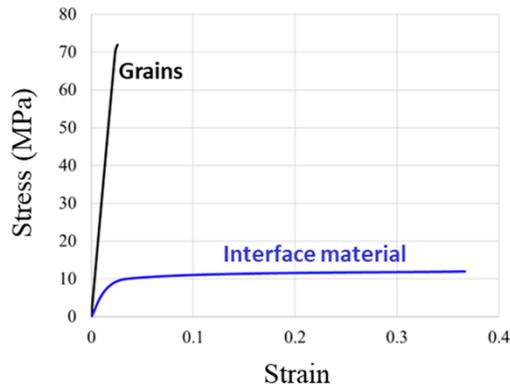

Intersection with (111) plane

Model range  $0.25 < f^{(g)} < 0.35$

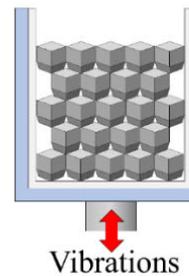

# Free-standing cohesive granular crystals

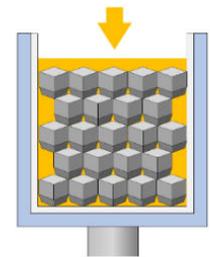

Desired interface behavior:

Granular Crystallization

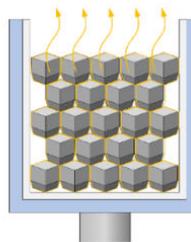

Emulsion of adhesive + ethanol

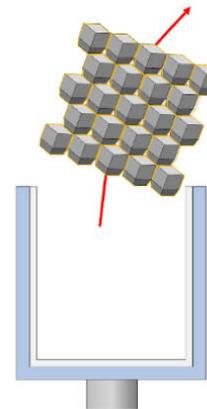

Selection: a methacrylate-based pressure-sensitive adhesive (PSA)

Ethanol Evaporation

Extraction

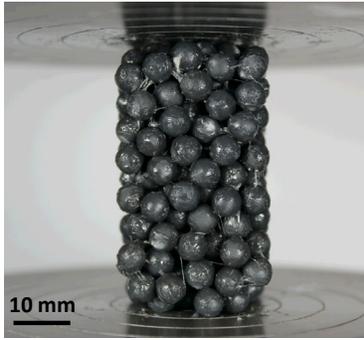

Navdeep Karuriya

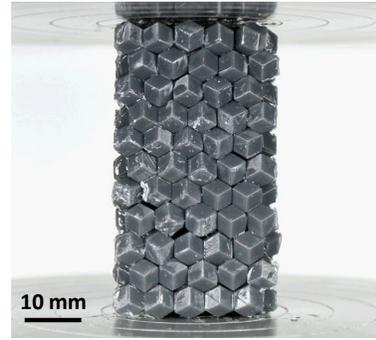

Jeremy Simoes

# Free-standing cohesive granular crystals

Randomly distributed spheres (RDS)

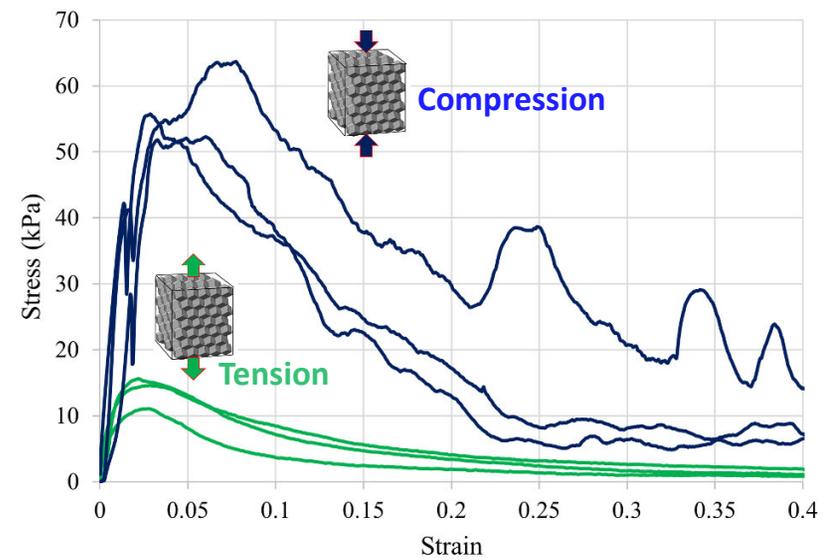

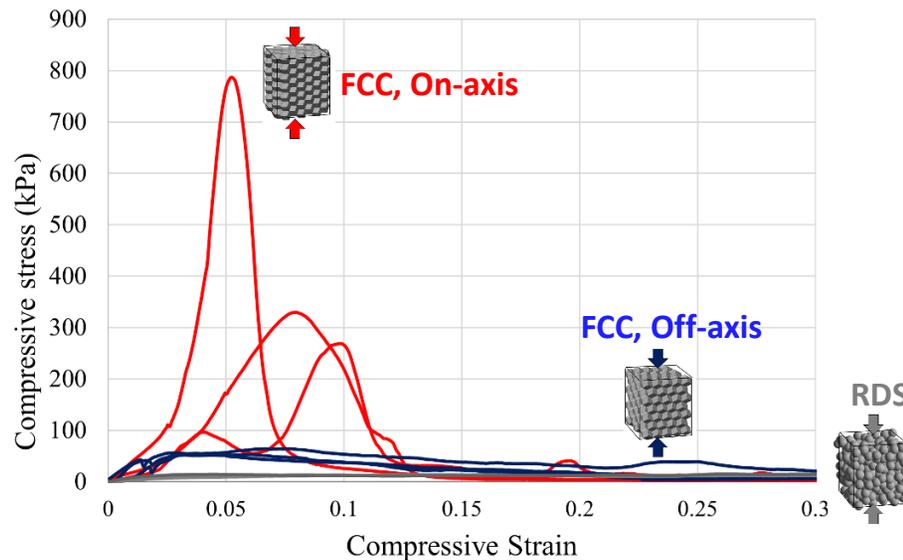

Off-axis FCC

On-axis FCC

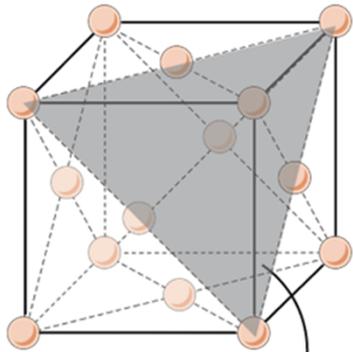

Off-axis FCC cohesive granular crystal

- **FCC crystal in compression: Slip along {111} or micro-buckling**
- **FCC crystal in compression: up to 60x stronger than randomly distributed spheres**

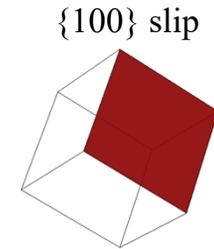

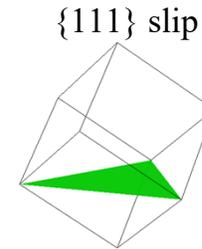

# FCC vs. HCP in classical metallurgy

Face-centered cubic  
(FCC) lattice

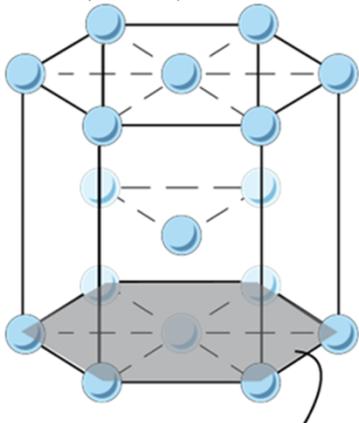

Close packing  
plane:  $\{111\}$

*Classical metallurgy for FCC:* Slip on  $\{111\}$  systems is the prominent deformation mechanism

Hexagonal Close packed  
(HCP) lattice

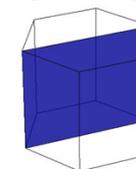

Close packing  
plane:  $\{0001\}$

*Classical metallurgy for HCP:* Less symmetries, more families of slip planes but fewer total available slip systems: higher yield strength.

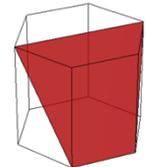

Basal slip  
 $[0001]$

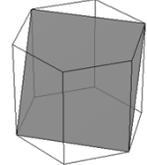

Prismatic  
 $[10-10]$

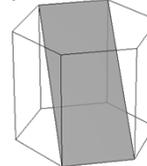

Pyramidal  $\pi 1$

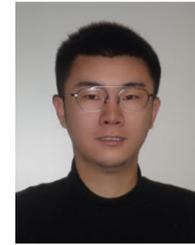

Pyramidal  $\pi 2$

Pyramidal  $\pi 3$

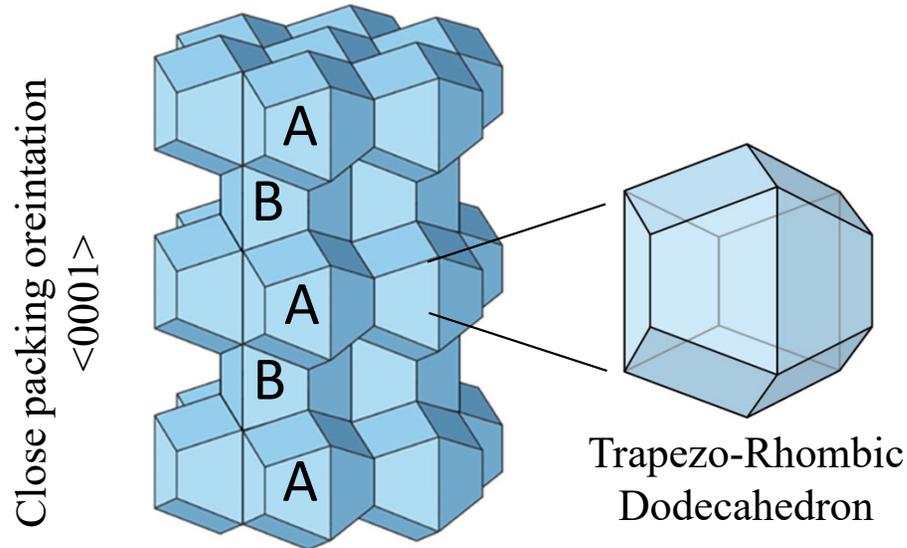

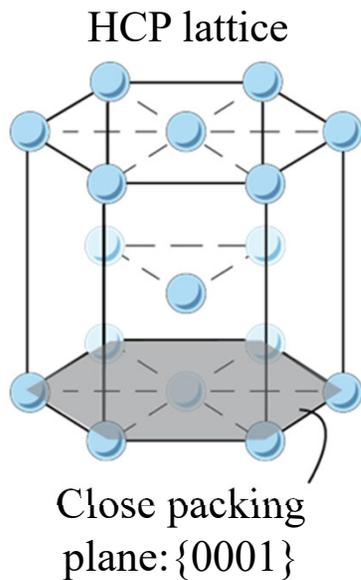

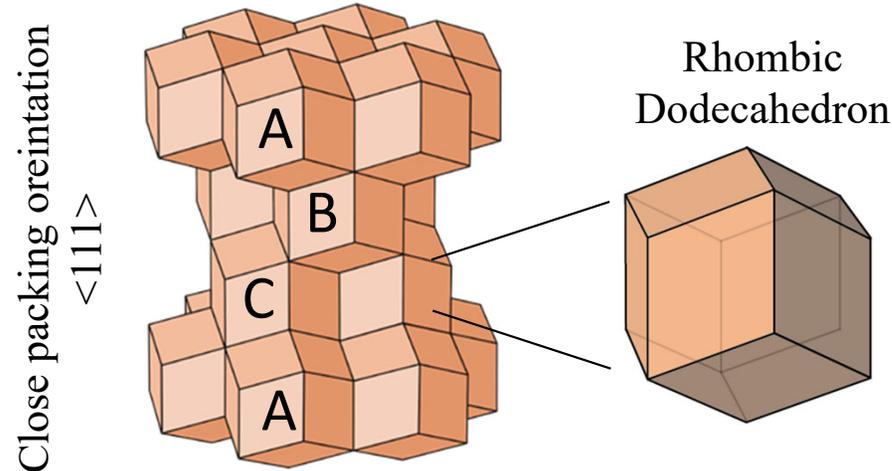

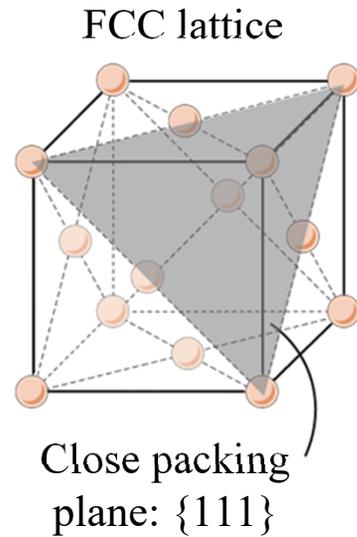

# FCC vs. HCP granular crystals

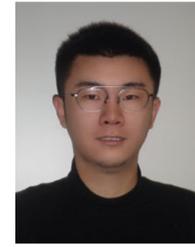

Tian Gao

Navdeep Karuriya

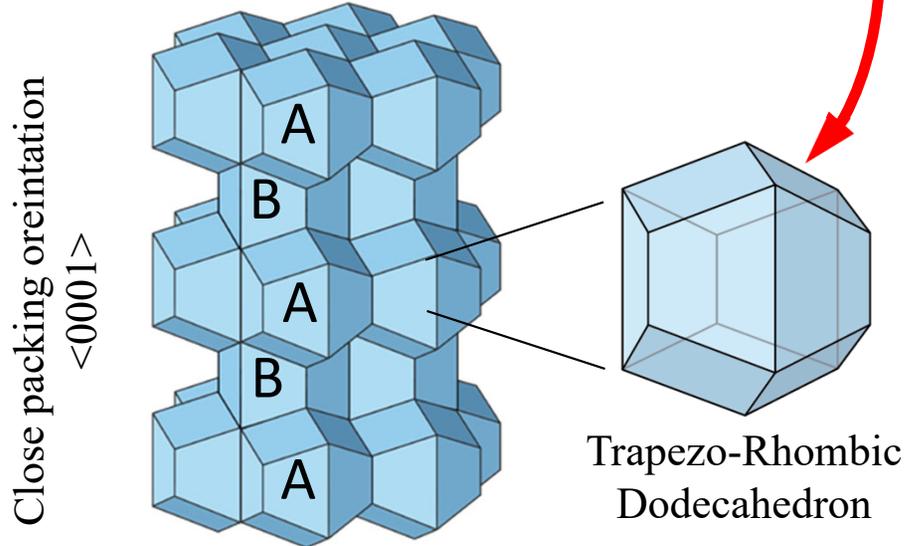

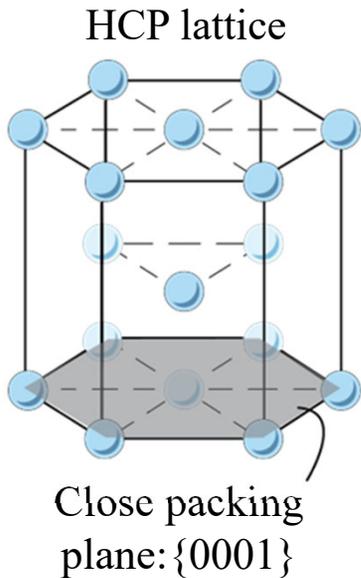

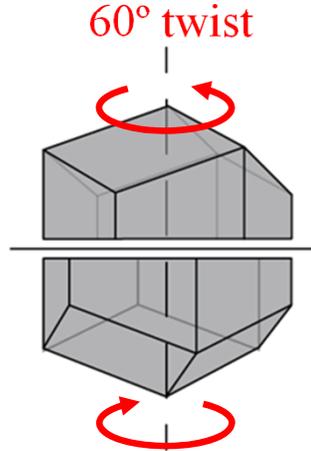

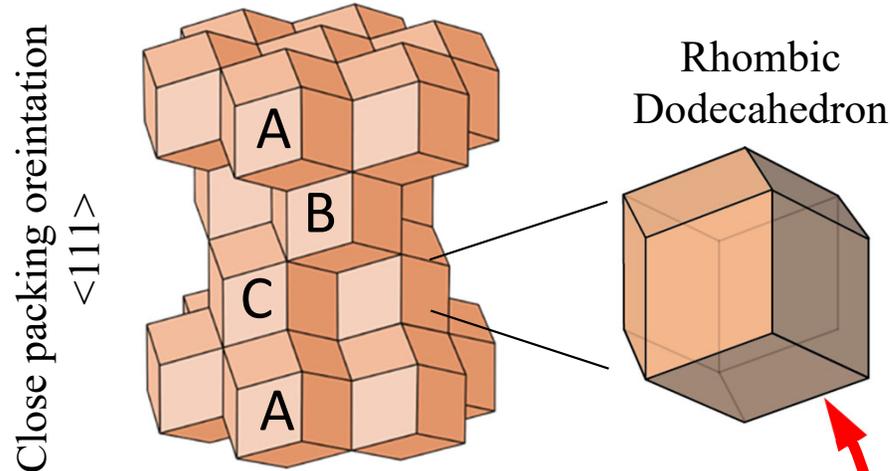

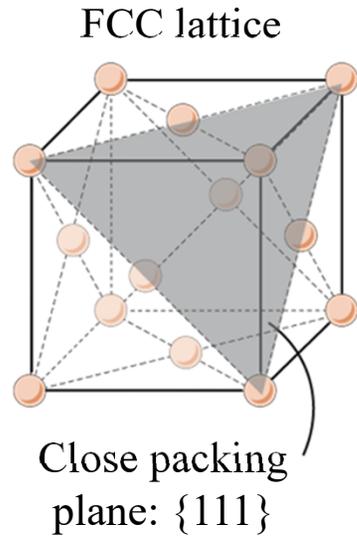

# FCC vs. HCP granular crystals

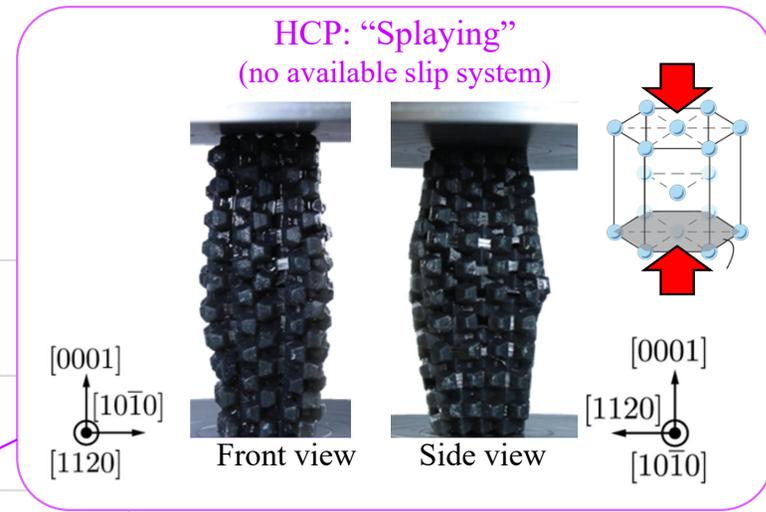

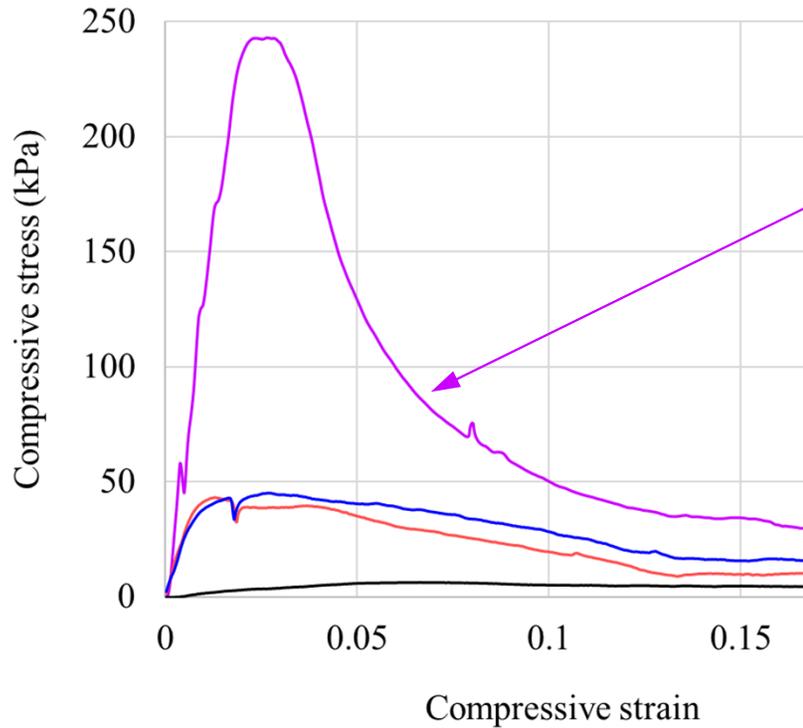

Tian Gao

Navdeep Karuriya

# Compression tests

HCP: Prismatic slip

FCC: {111} slip

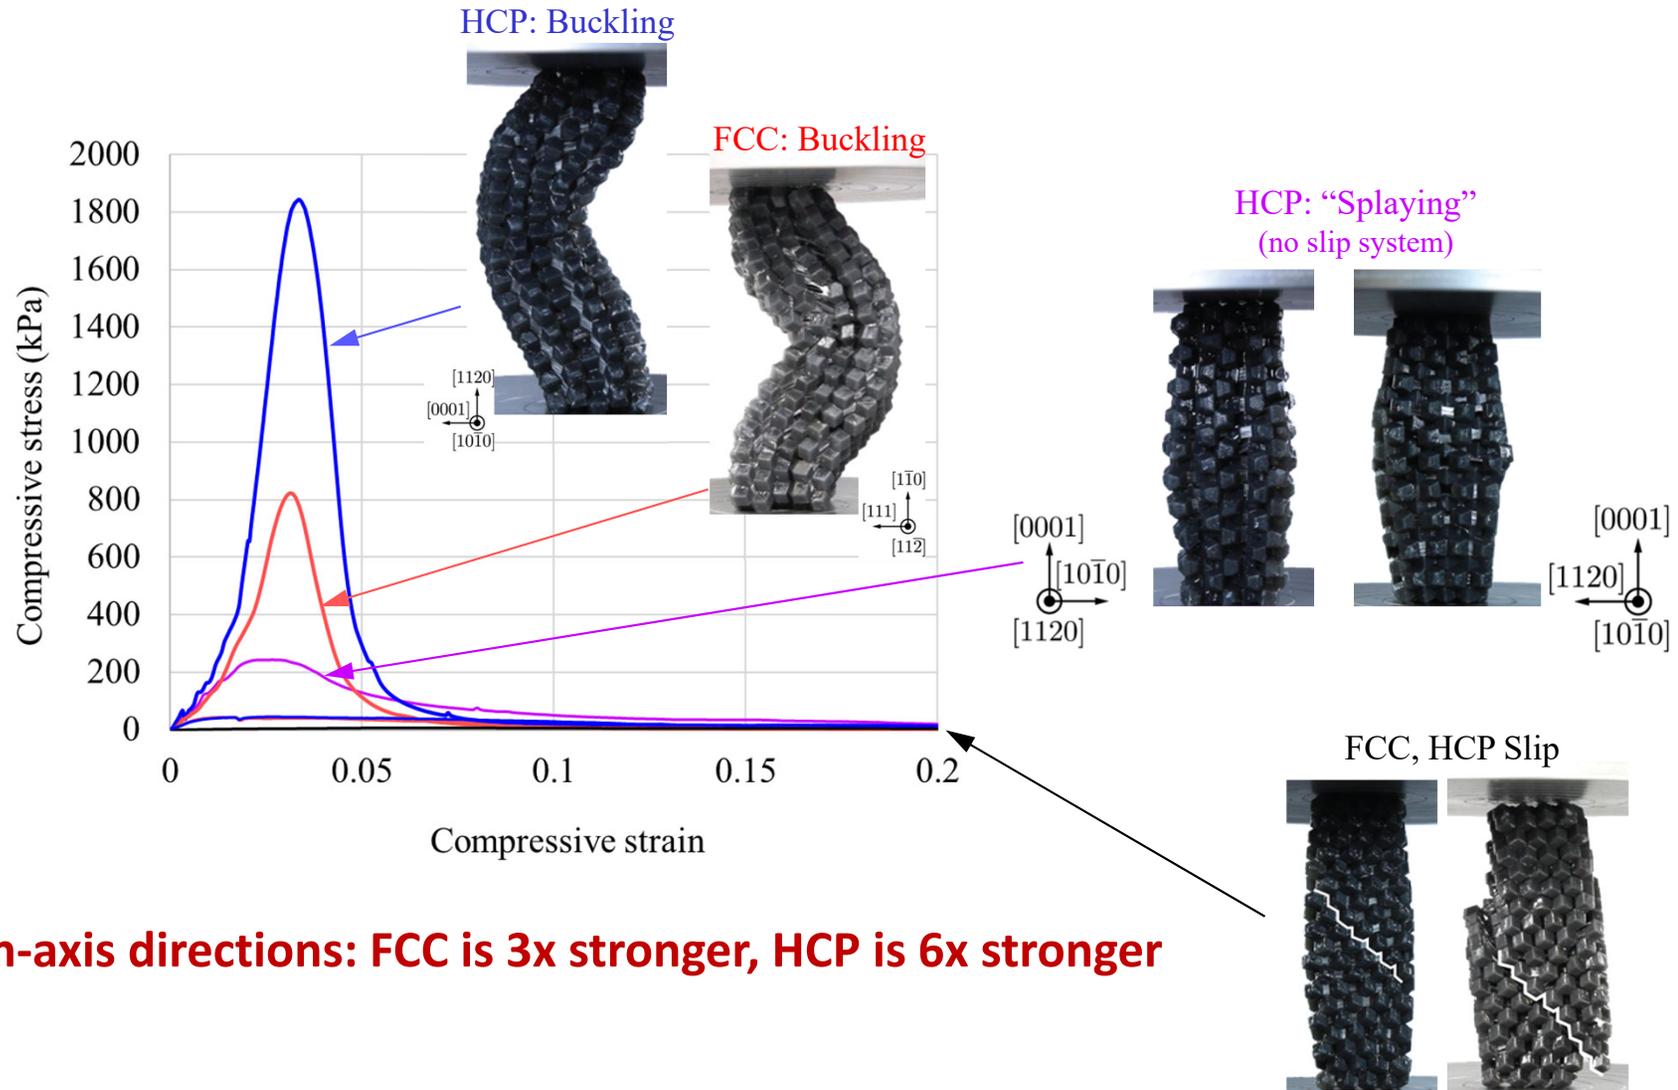

RPS

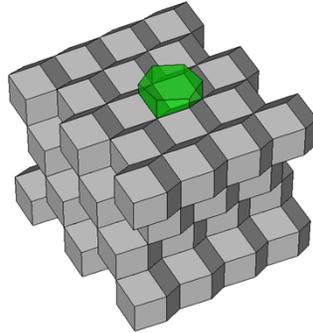

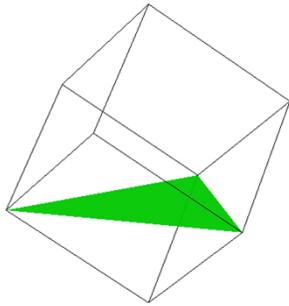

- **FCC / HCP Crystals 8-10 times stronger than RDS**
- **HCP / prismatic slip and FCC / {111} slip have about the same strength**
- **HCP compression along [0001]: 5x stronger with homogenous "splaying" deformation (no slip plane)**

# Compression tests

# Comparison FCC-HCP

FCC

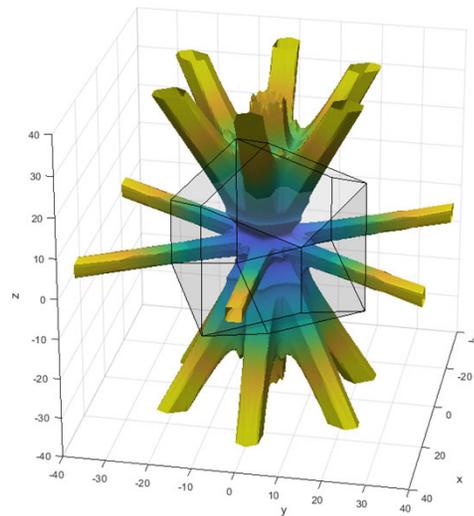

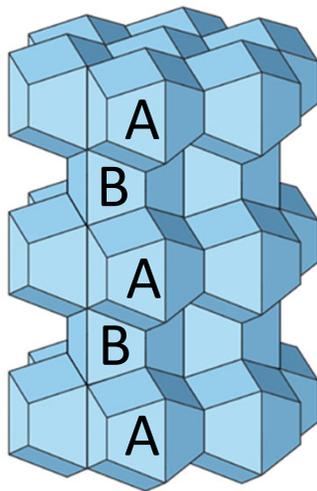

Average strength

$$\langle \sigma_y \rangle / \tau_0 = 11.4$$

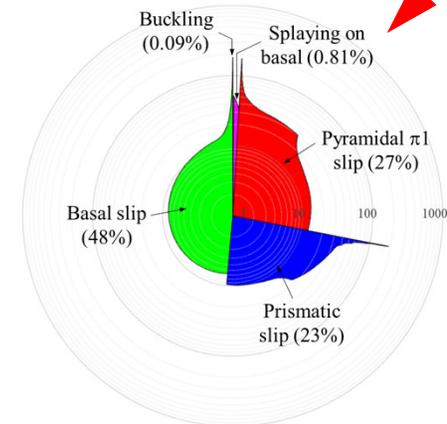

HCP

Average strength

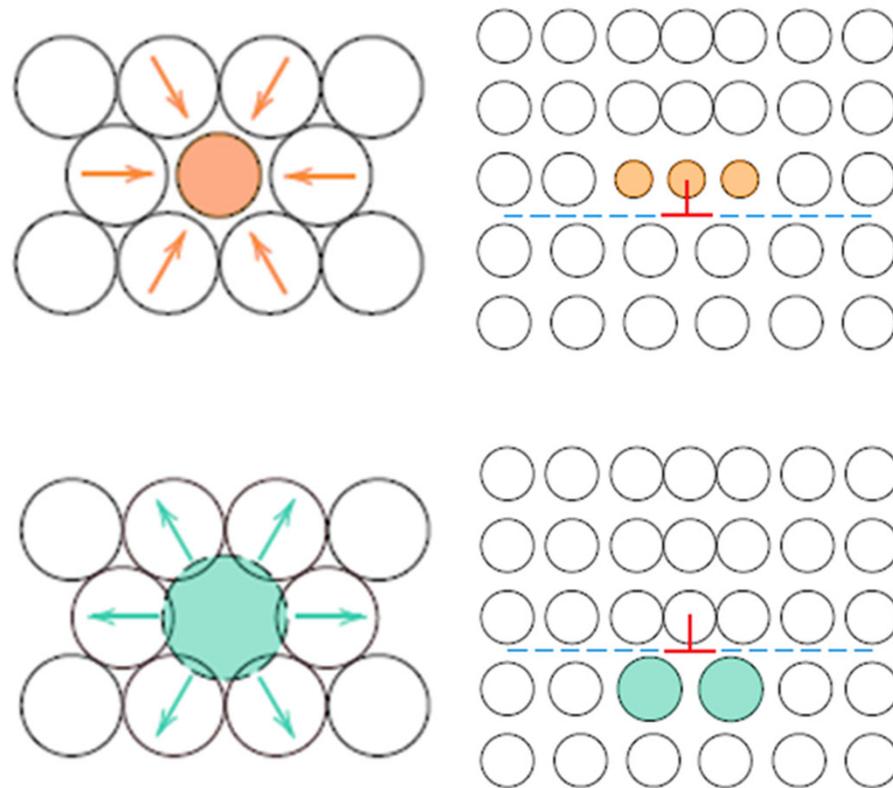

$$\langle \sigma_y \rangle / \tau_0 = 16.3$$

**HCP = On average 50% stronger than FCC, broader variety of failure modes**

# Solid solution strengthening in classical metallurgy

Substitution atoms create tensile or compressive lattice strains that pin dislocations

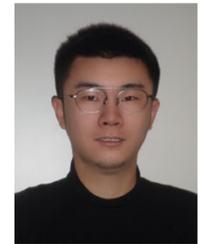

*Callister, Materials Science and Engineering*

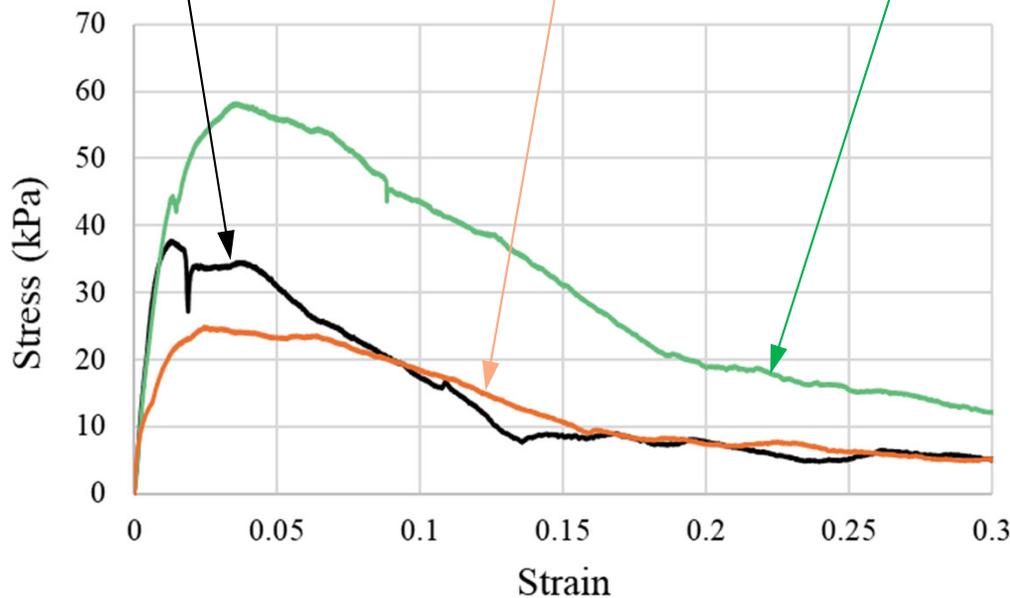

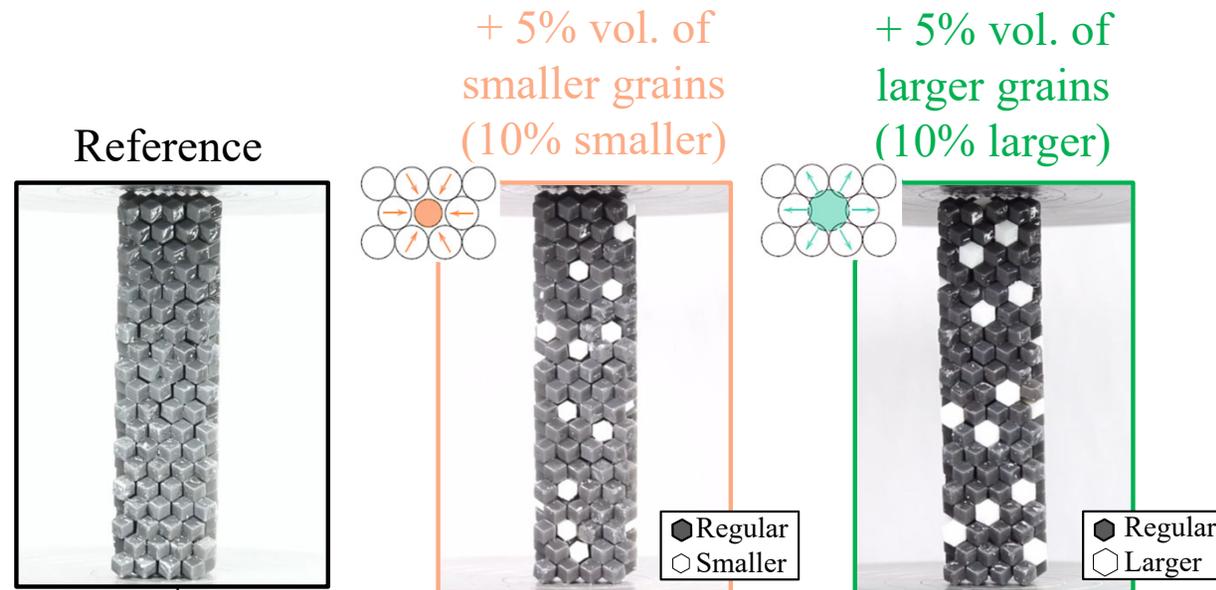

# Granular solid solution strengthening?

Navdeep Karuriya

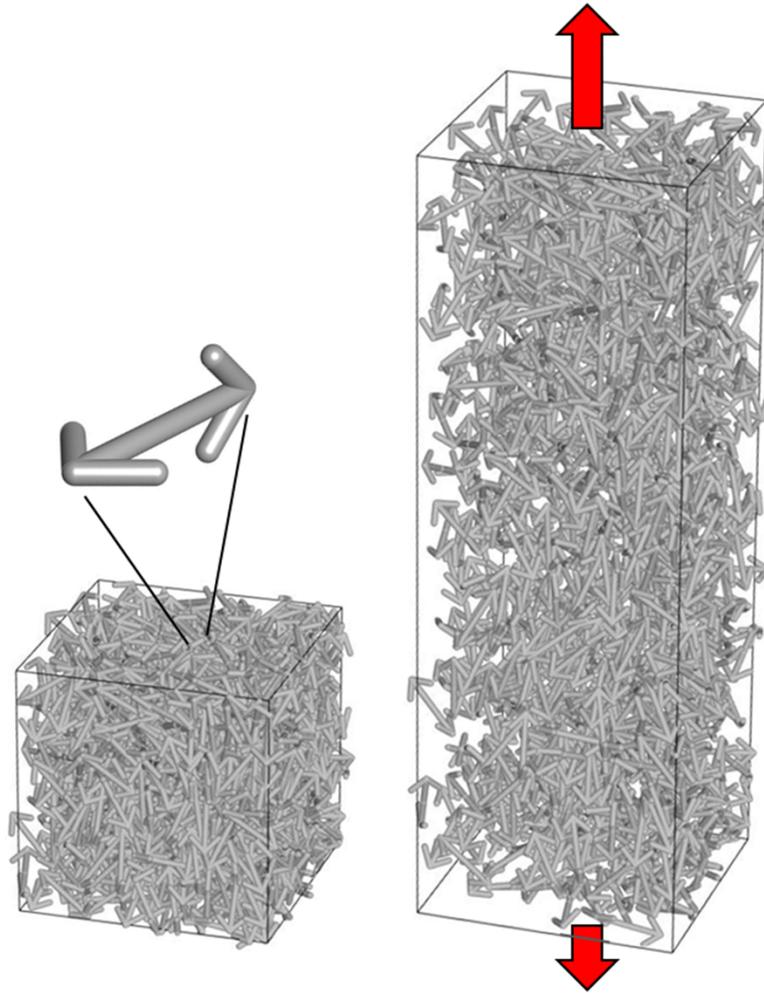

Tian Gao

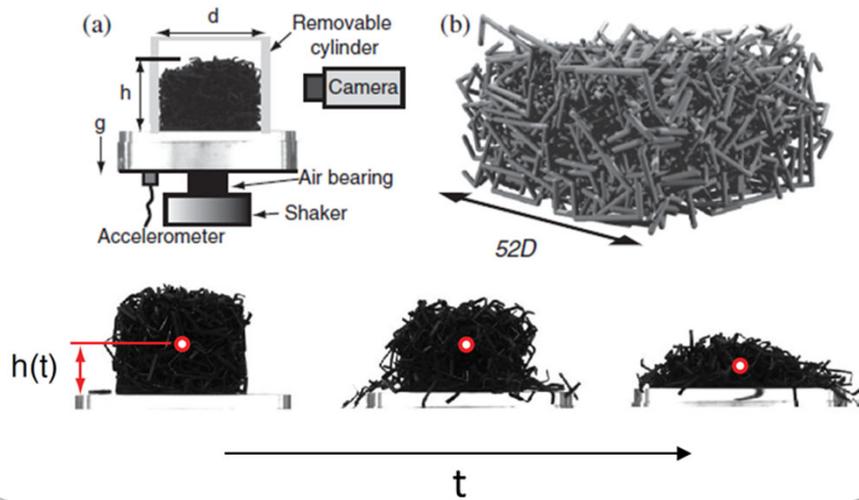

- **Smaller grains: strength decreases**
- **5% vol. of larger grains (10% larger): strength increases by 50%**
- **Increase the size of larger grains: cannot assemble crystal**

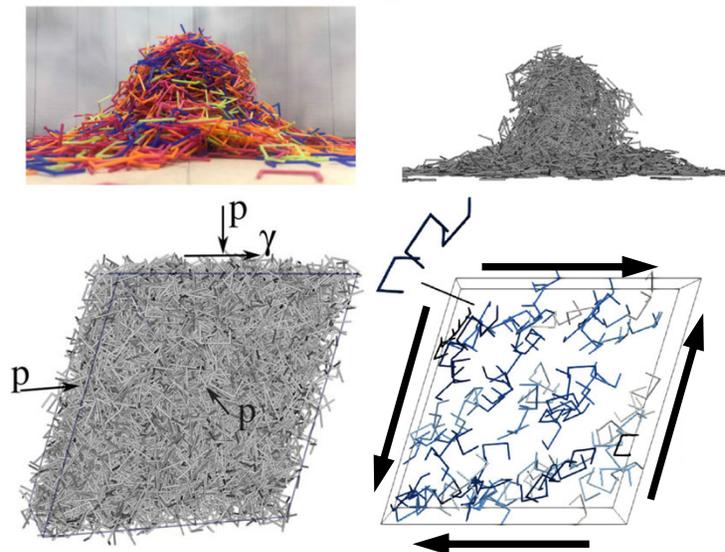

# Entangled granular materials with tensile strength

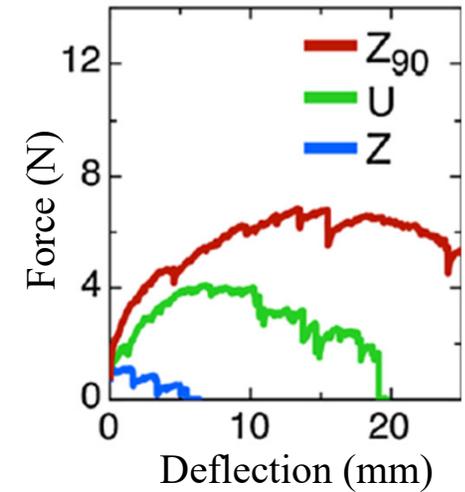

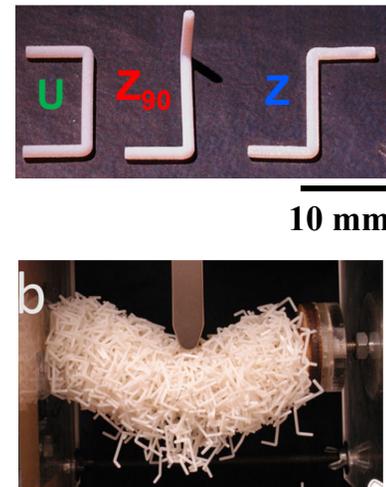

**Free standing columns of entangled staples**  
(Gravish, Franklin, Hu and Goldman *PRL* 2012)

**Stress transmission in entangled granular structures**  
(Karapiperis, Monfared, Buarque de Macedo, Richardson and Andrade, *Granular Matter* 2022)

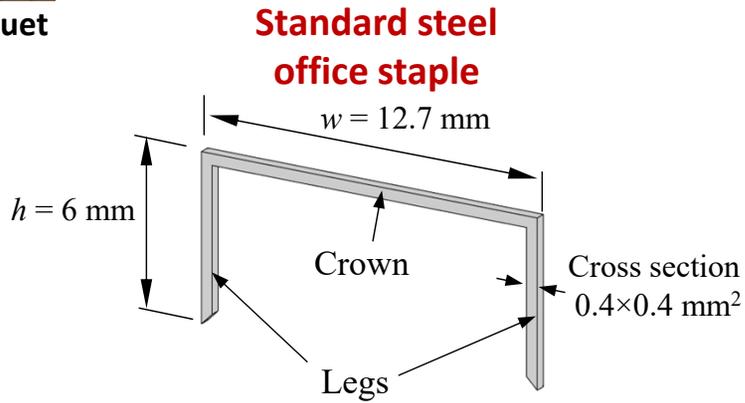

**Strong bundles of “Z shape” particles**  
(Murphy, Jaeger, *Granular Matter* 2016, Murphy, Roth, Peterman, Jaeger, *Architectural Design* 2017)

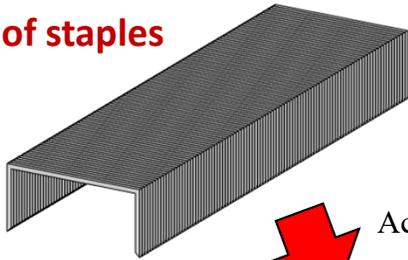

# Our first model material: Staples

Vivien Fouquet

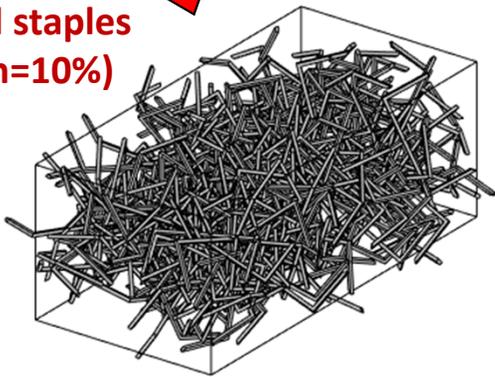

**A stick of staples**

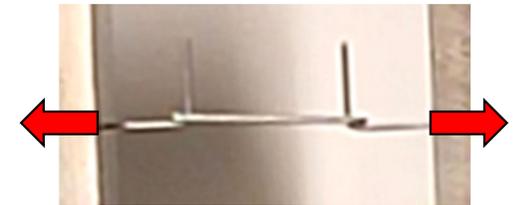

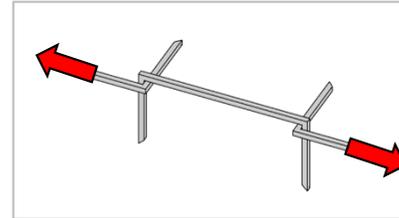

Acetone bath

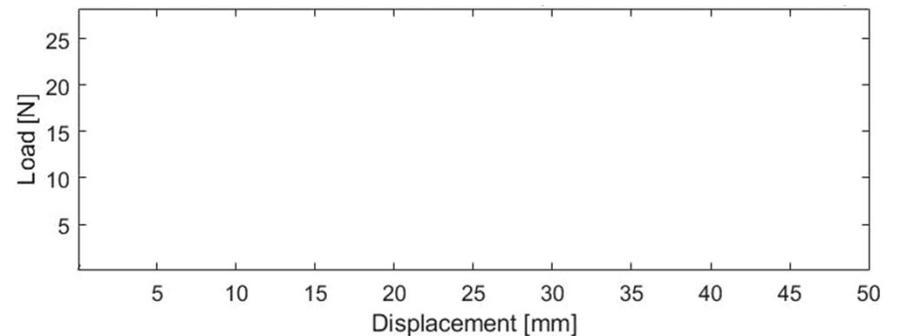

**Randomly distributed staples  
(typical solid fraction=10%)**

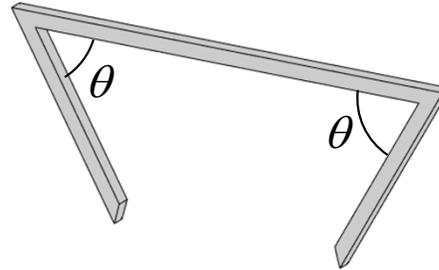

**Staple pair strength test: Strength =  $9 \pm 4 \text{ N}$   
Failure occurs by elastic deformation + slipping or rotation and then unstable snap**

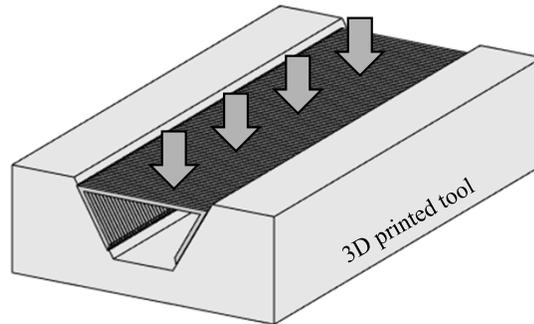

**Tensile test on a bundle of 2000 staples:  
Strength =  $28 \pm 14 \text{ N}$**

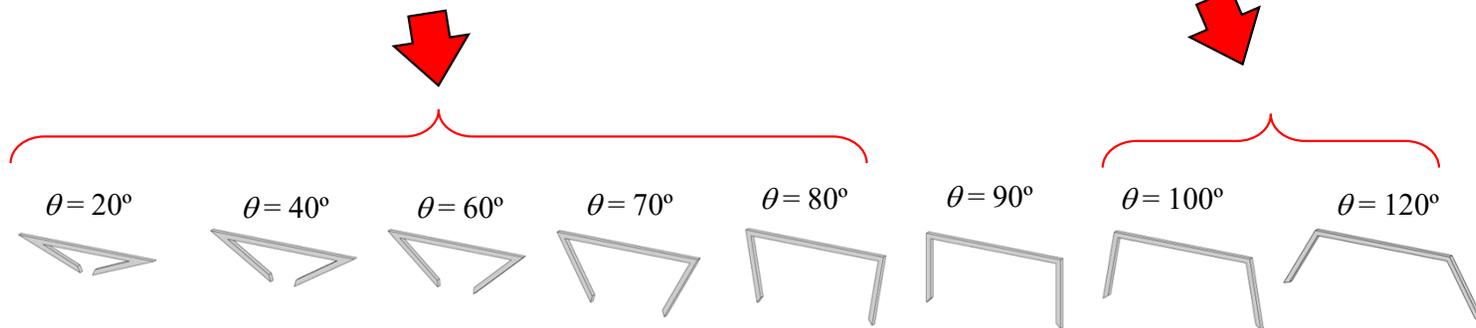

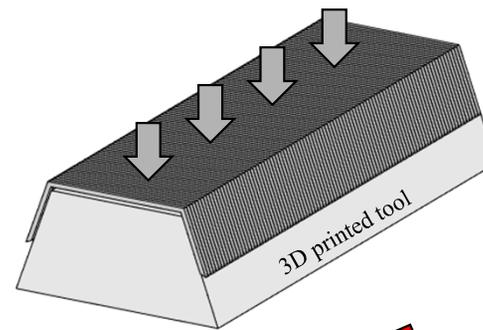

# Manipulating the crown-leg angle $\theta$

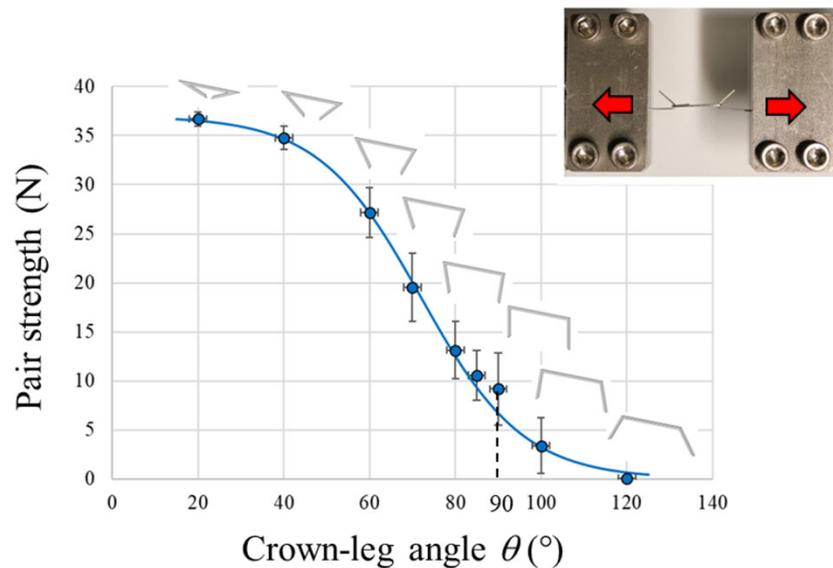

**Closing  $\theta$ :**

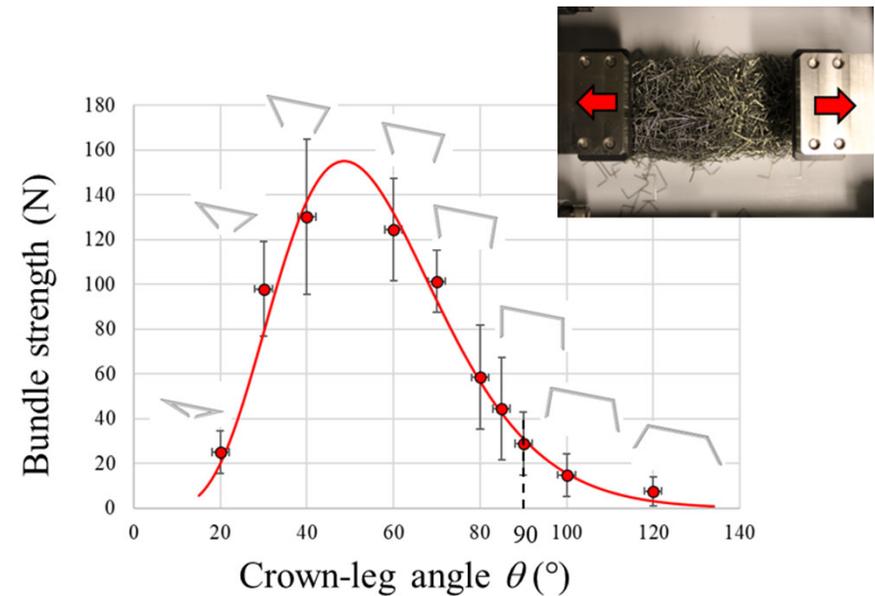

**Opening  $\theta$ :**

## Staple pair strength

## Staple bundle strength

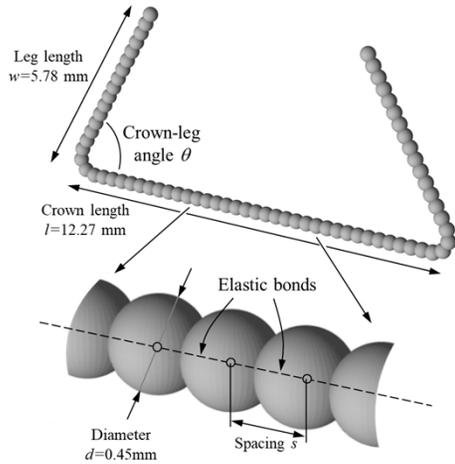

- Strength of a pair of 90° staples ~ 9N
- Closing the angle amplifies strength up to 4x
- Opening the angle rapidly leads to vanishing strength

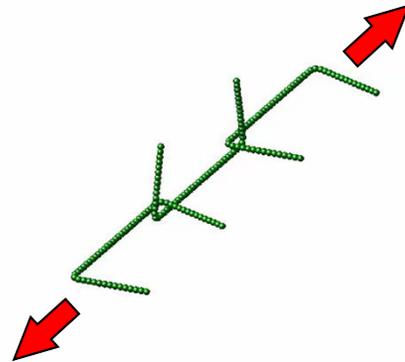

- Strength of a bundle of 90° staples ~ 28 N
- Closing the angle amplifies bundle strength up to 4.5x
- Maximum strength at angle  $\theta \approx 40-60^\circ$

# Discrete Element Method (DEM)

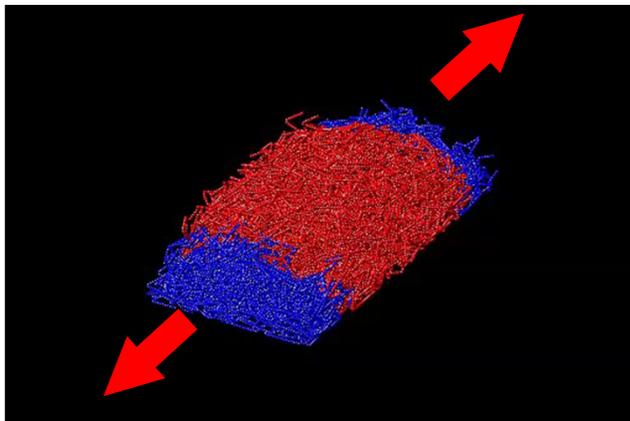

## Overlapping sphere model with elastic bonds (LAMMPS)

## Tensile DEM on a chain of staples

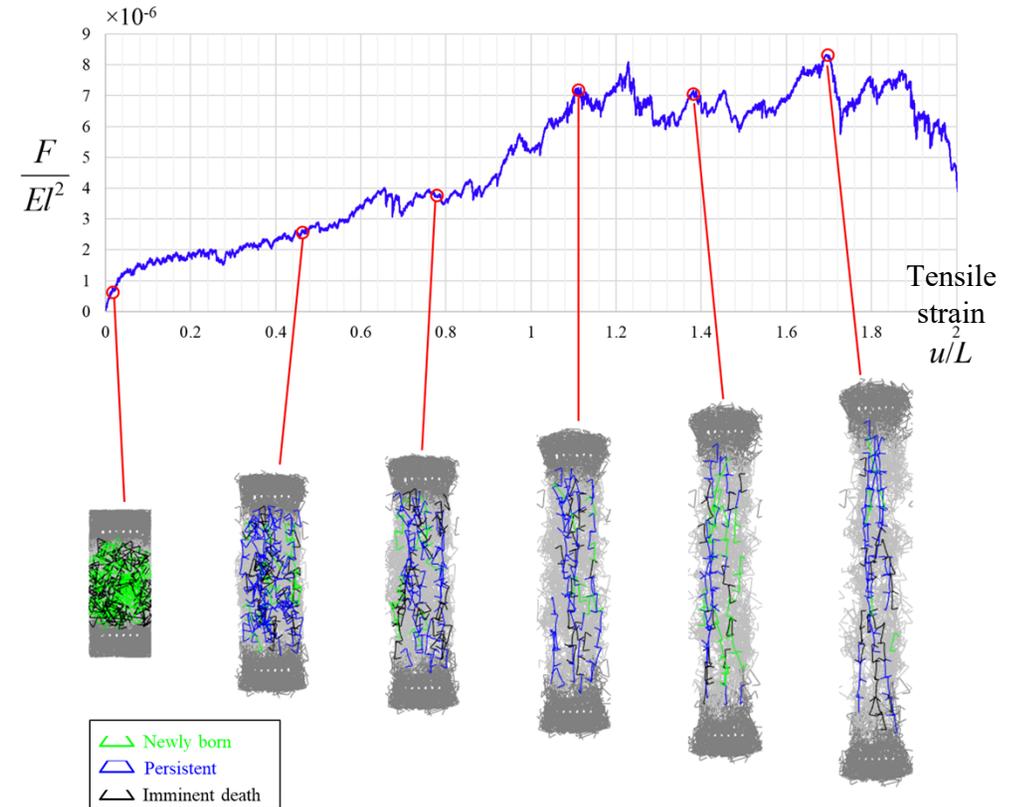

## Tensile DEM of a bundle of 2000 staples

Tensile stress

## Force extension curve of bundle

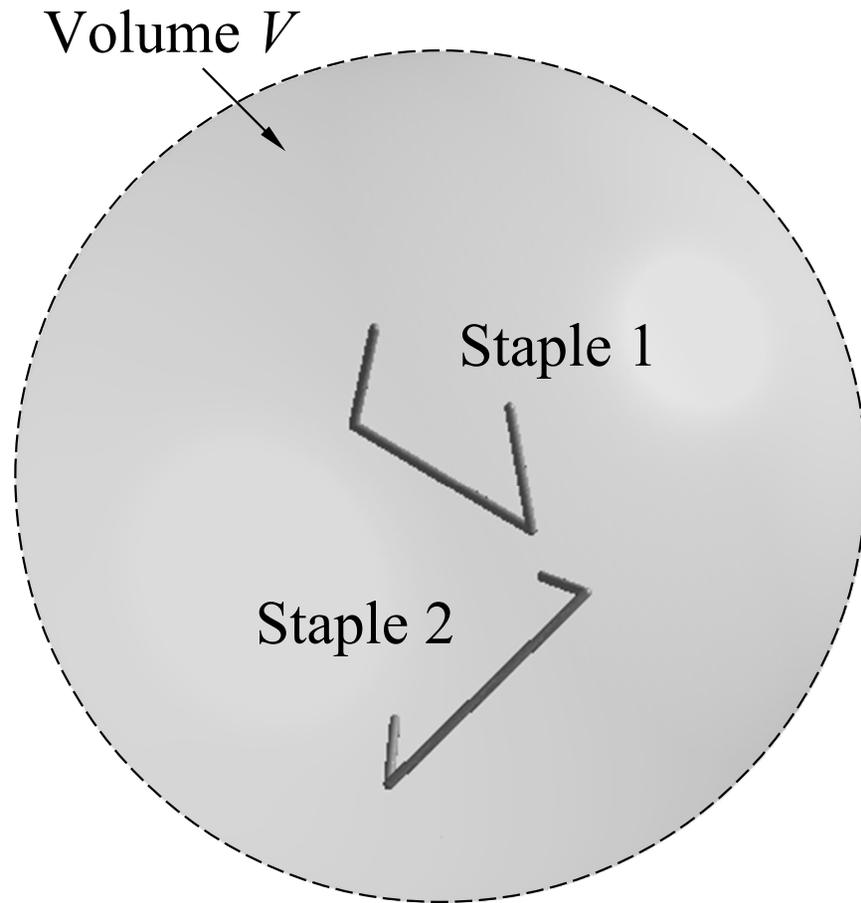

- DEM model captures staple-staple interactions, large deformations in the bundle
- Tensile force lines are highly dynamic: As deformation increases they appear, break, others force lines appear and take over

"Tunable entanglement and strength with engineered staple-like particles: Experiments and discrete element models" S. Pezeshki, Y. Sohn, V. Fouquet and F. Barthelat, JMPS 2025

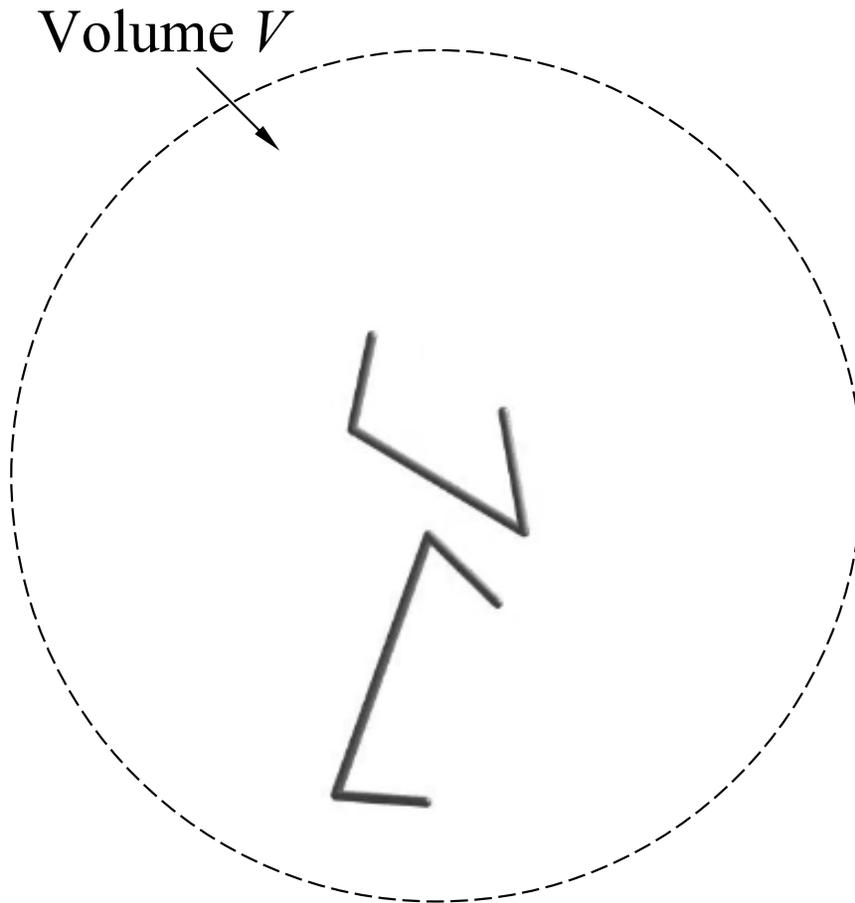

Saeed Pezeshki

# What can we learn from two staples?

# What can we learn from two staples?

**Staple 1:** fixed  
**Staple 2:** Random position & orientation within volume  $V$

**Monte Carlo ( $N=10^6$ ):**

Excluded volume      **Probability of collision**

$$V_{ex} = p_c V$$

**Volume fraction of staples**

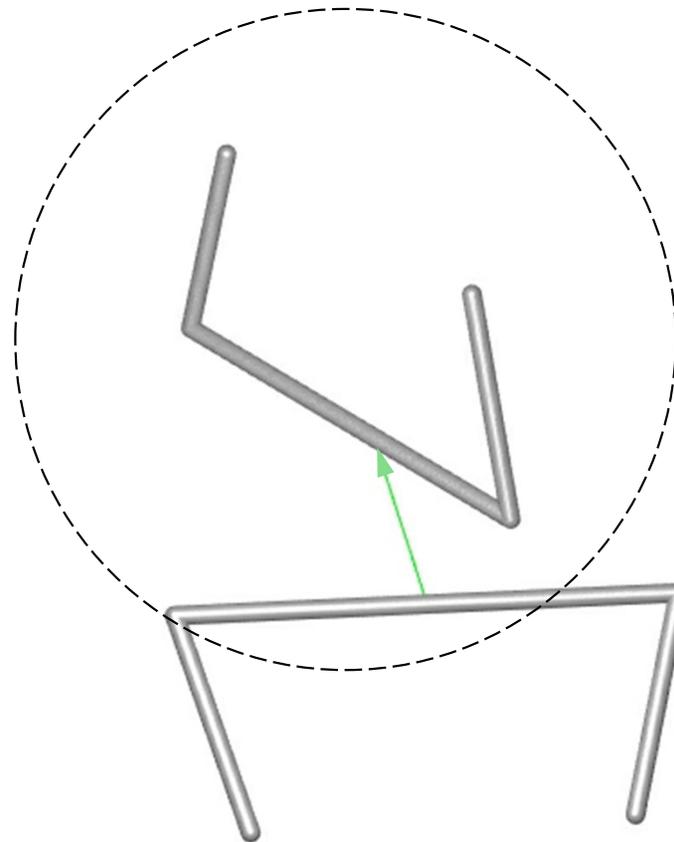

$$\phi \approx \frac{10}{V_{ex}}$$

Philipse *Langmuir* 1996

Gravish, Franklin, Hu and Goldman *PRL* 2012

# What (more) can we learn from two staples?

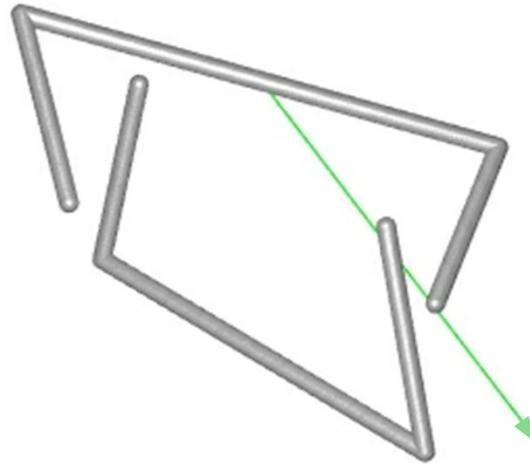

Sphere volume  $V_{ex}$

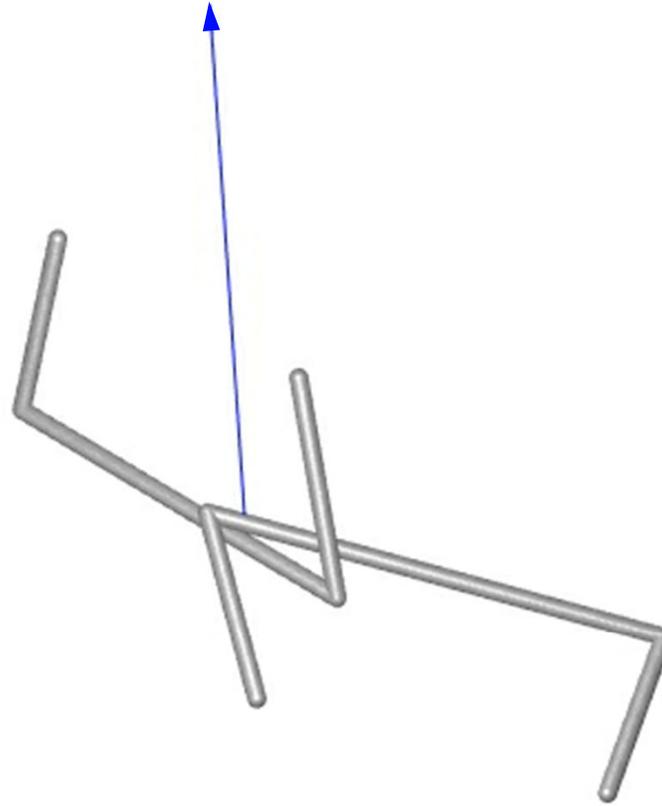

**(here staple 2 does not entangle with staple1)**

**Staple “visibility”:**

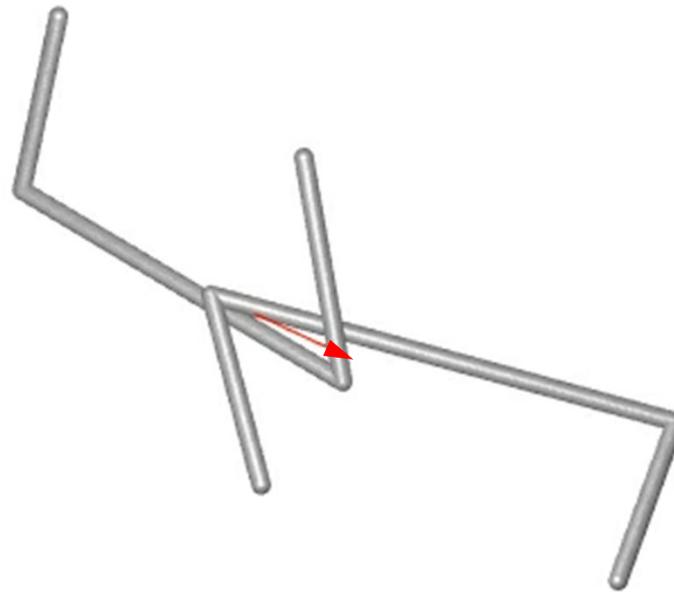

probability  $p_v$  of colliding with another staple

**If visible, staple 2 may  
“engage” with staple 1**

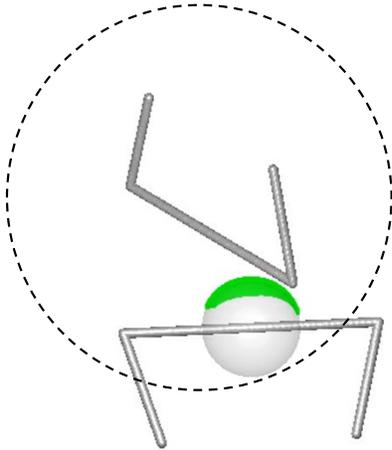

**After a “rebound”,  
staple 2 may  
disengage, or...**

**Staple 2 may  
entangle deeper  
with staple 1**

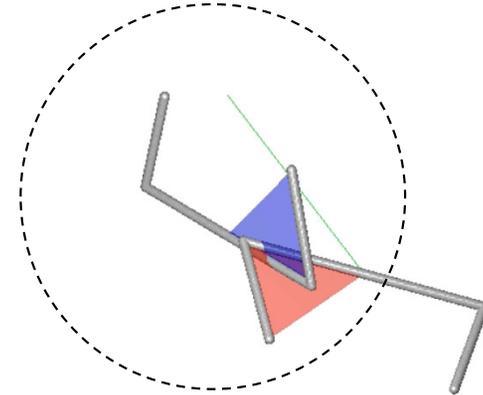

# Entanglement Density

Sphere volume  $V_{ex}$

**Staple “visibility”:** probability  $p_v$  of colliding with another staple

Sphere volume  $V_{ex}$

**Staple entanglement:** probability  $p_t$  of two staples to entangle

**Monte Carlo ( $N=10^6$ ):**

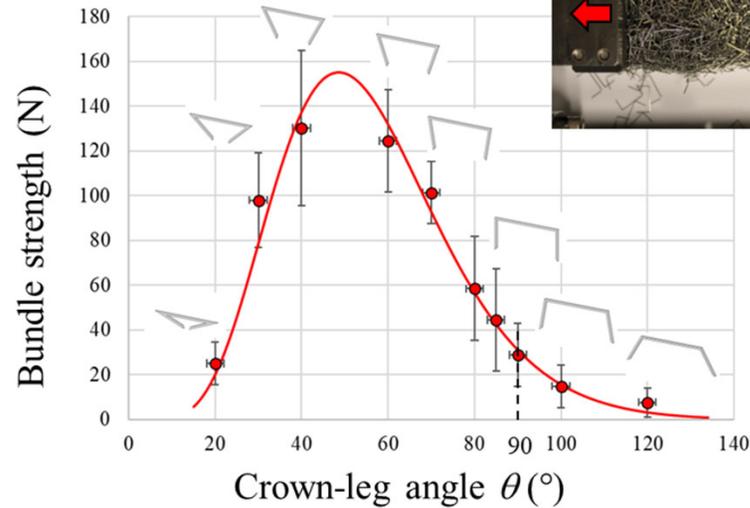

**Average entanglement density:**  $\phi_t = p_v p_t \phi$

Average number of entangled staples in a  $l \times l \times l$  volume ( $l$ =size of the staple)

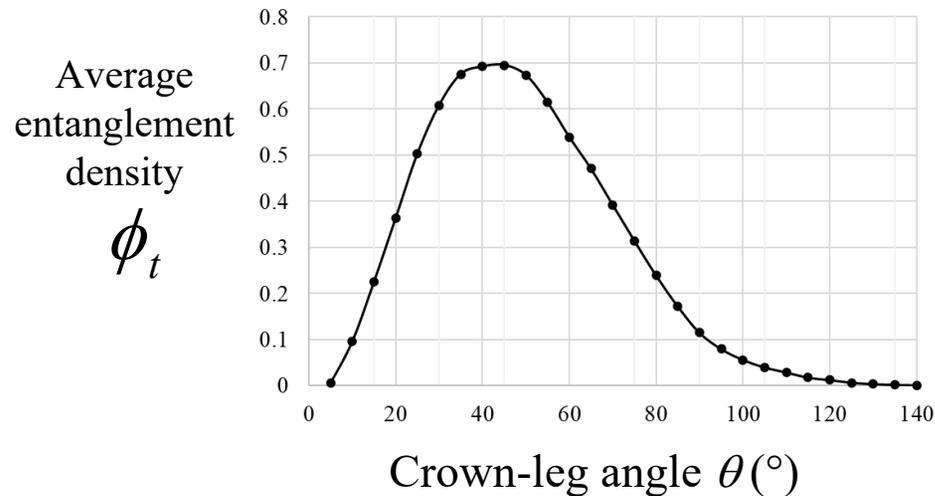

Sohn, Pezeshki and Barthelat, to appear in *Granular Matter*

# Effect of crown-leg angle

## Experiments:

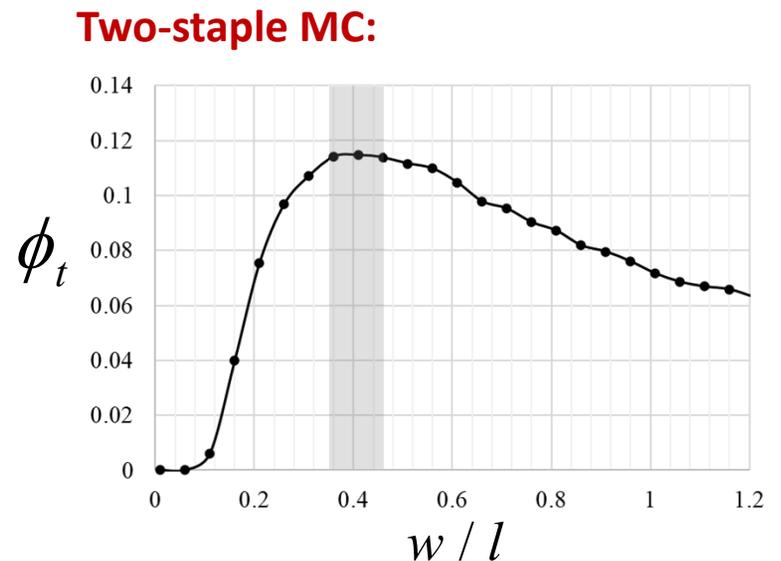

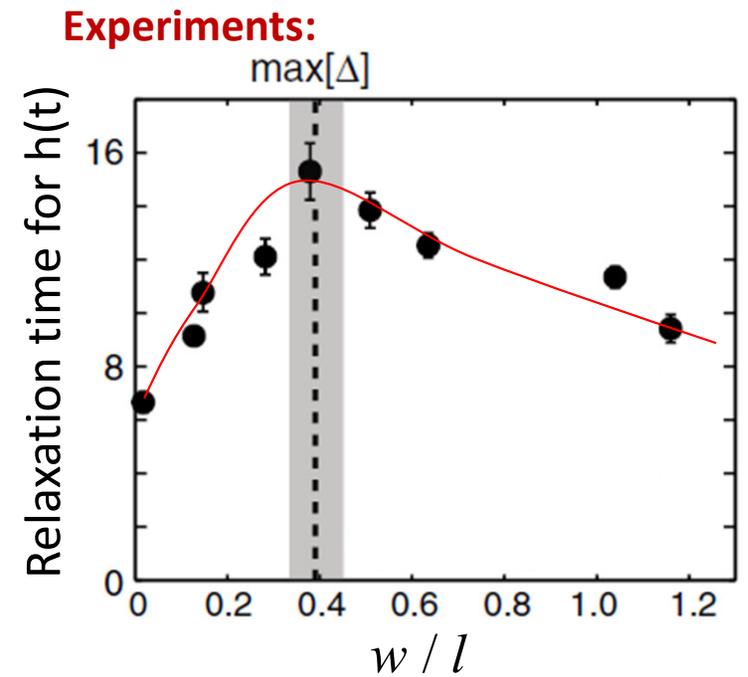

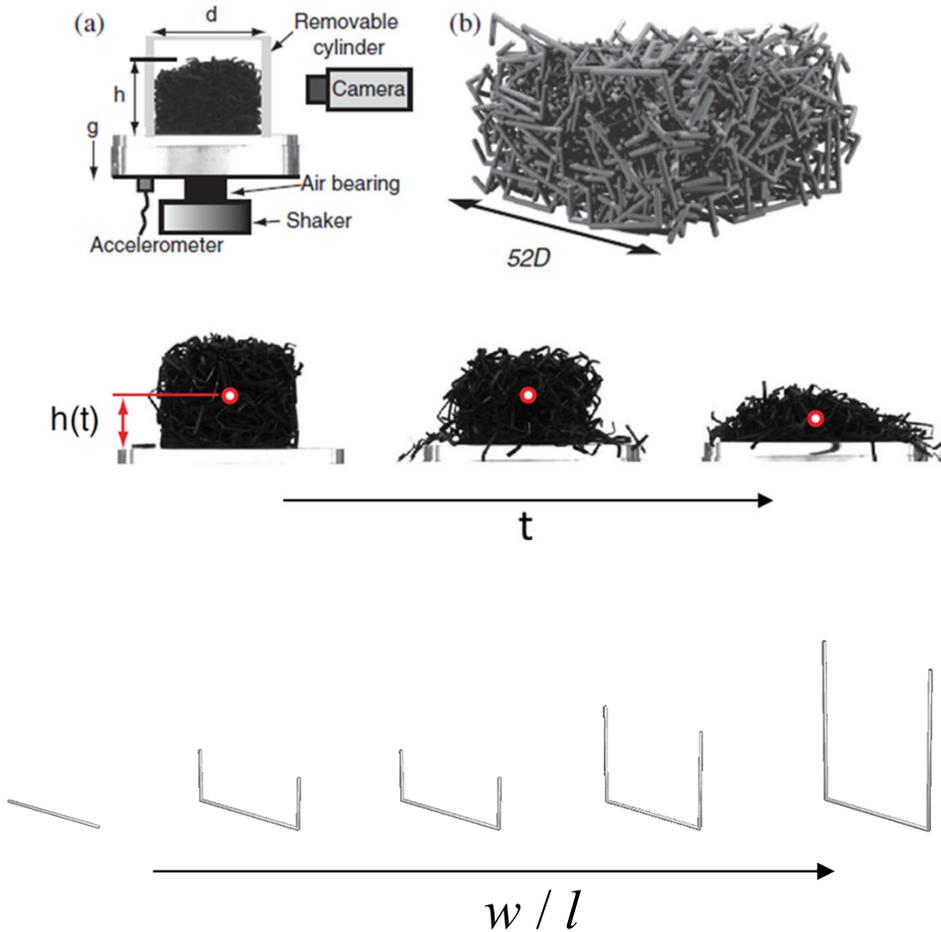

## Two-staple Monte Carlo:

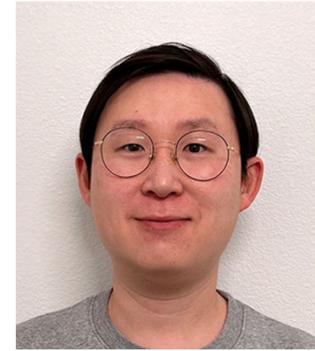

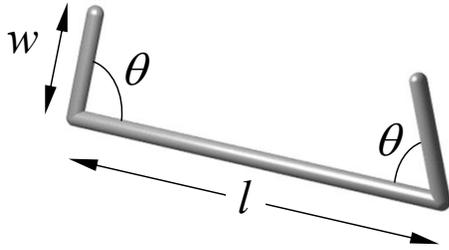

# Effect of leg length

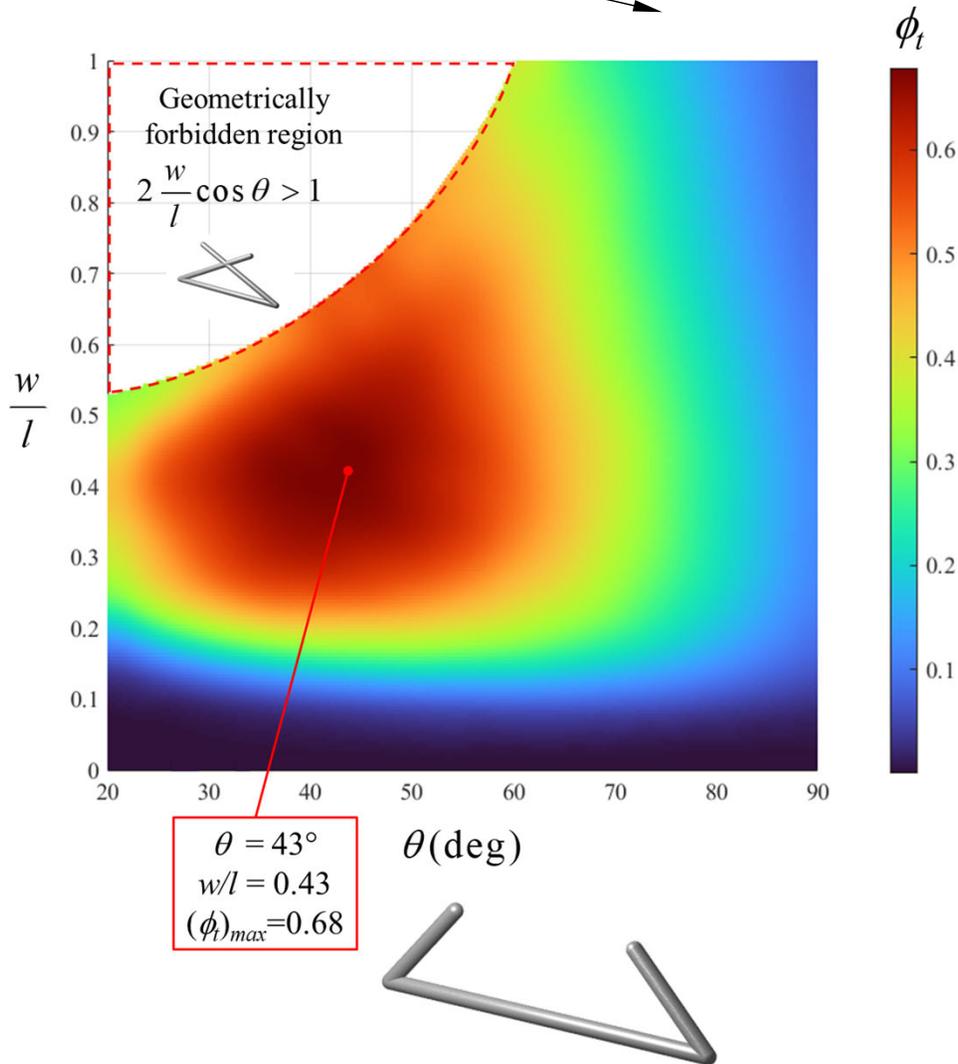

Gravish, Franklin, Hu and Goldman:  
 "Entangled Granular Media" *PRL* (2012)

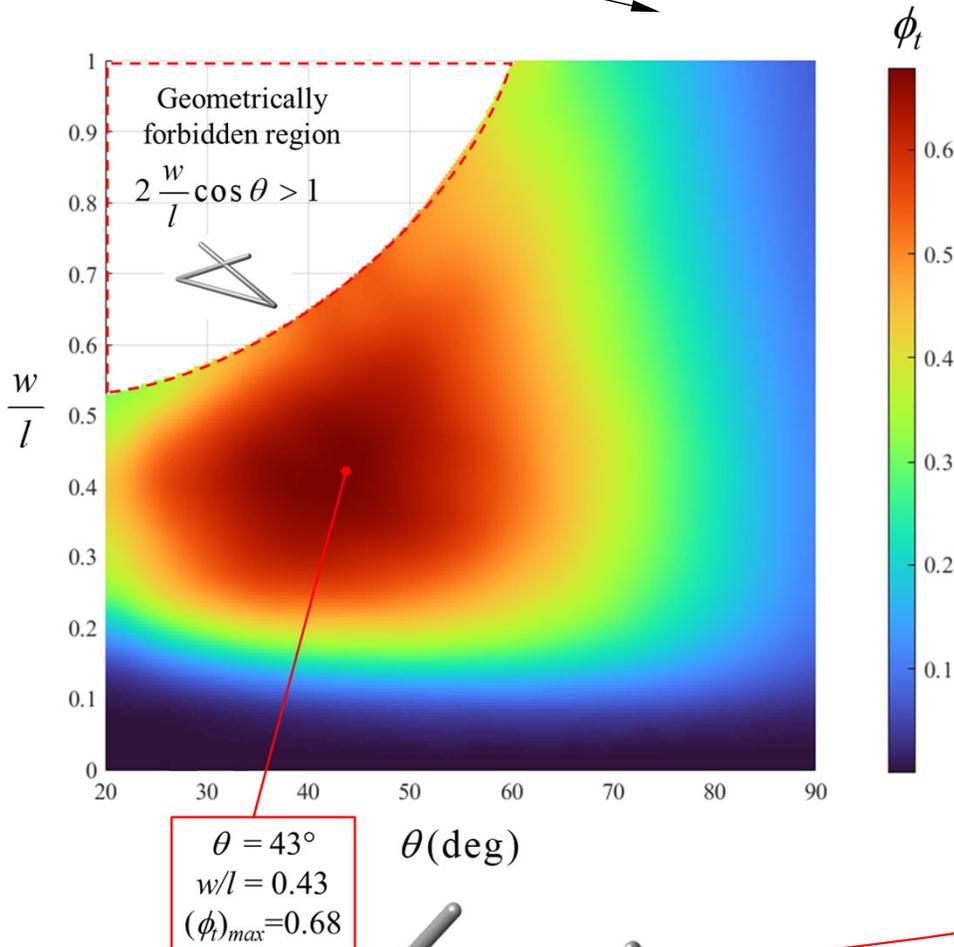

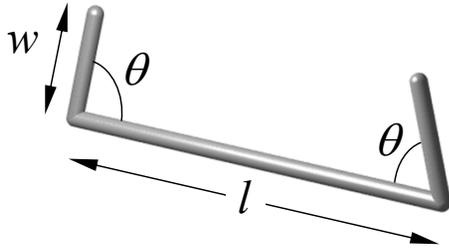

# Designing / optimizing particle shape

Youhan Sohn

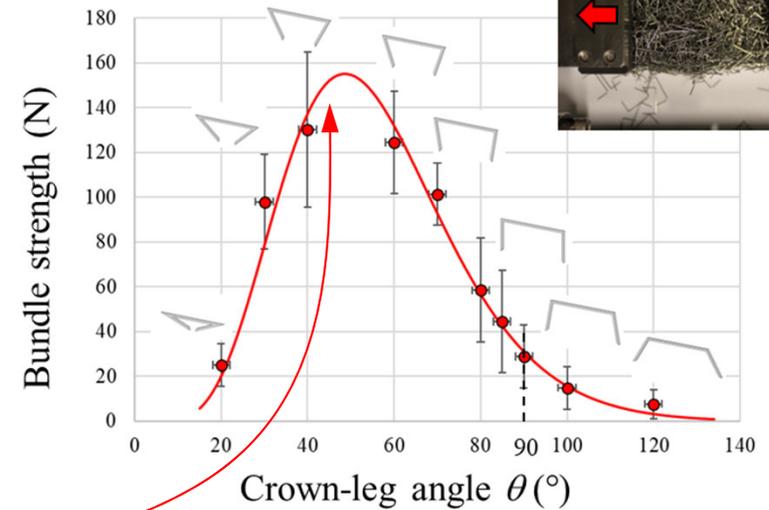

# Designing / optimizing particle shape

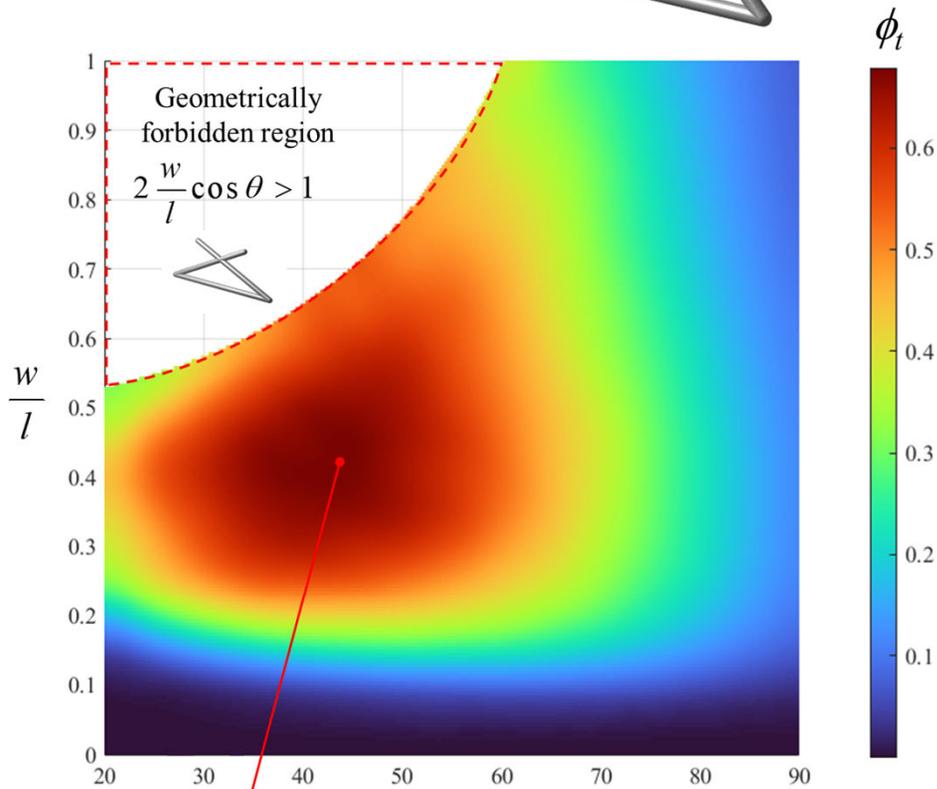

Youhan Sohn

## Experiments:

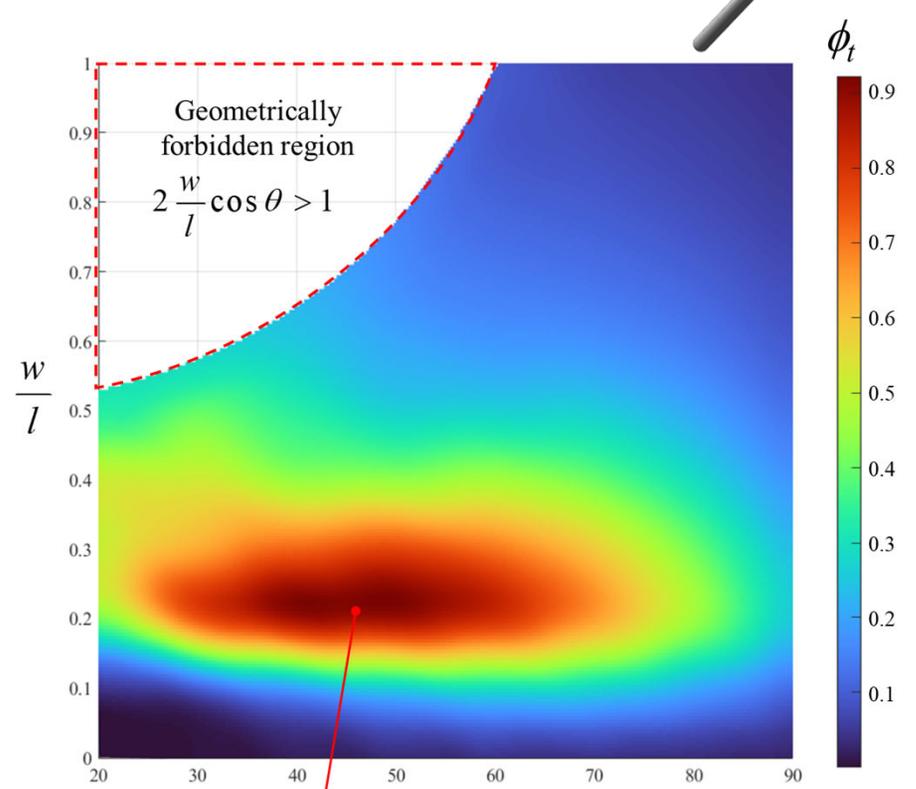

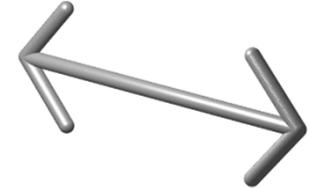

# Designing / optimizing particle shape

C-shape staple:

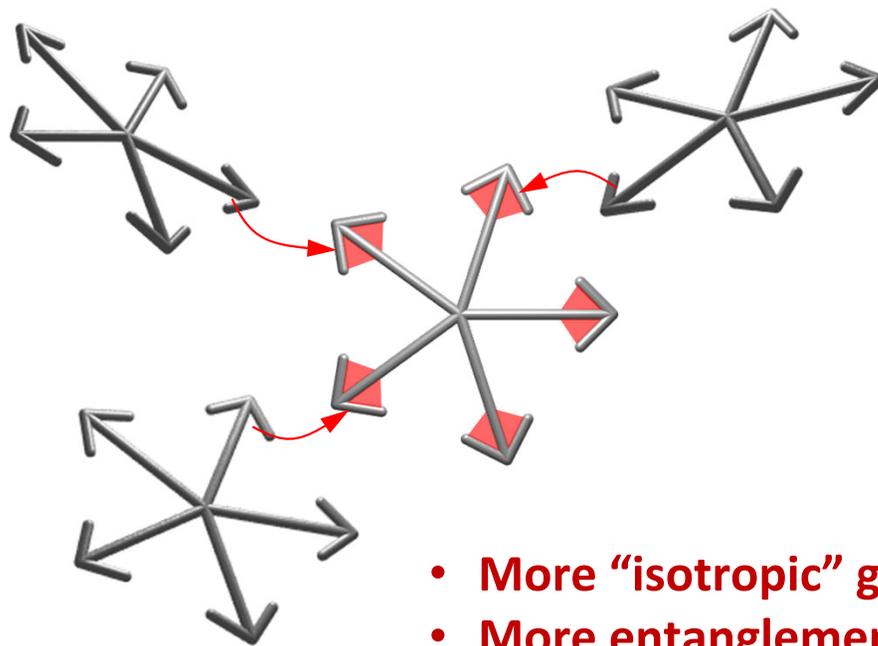

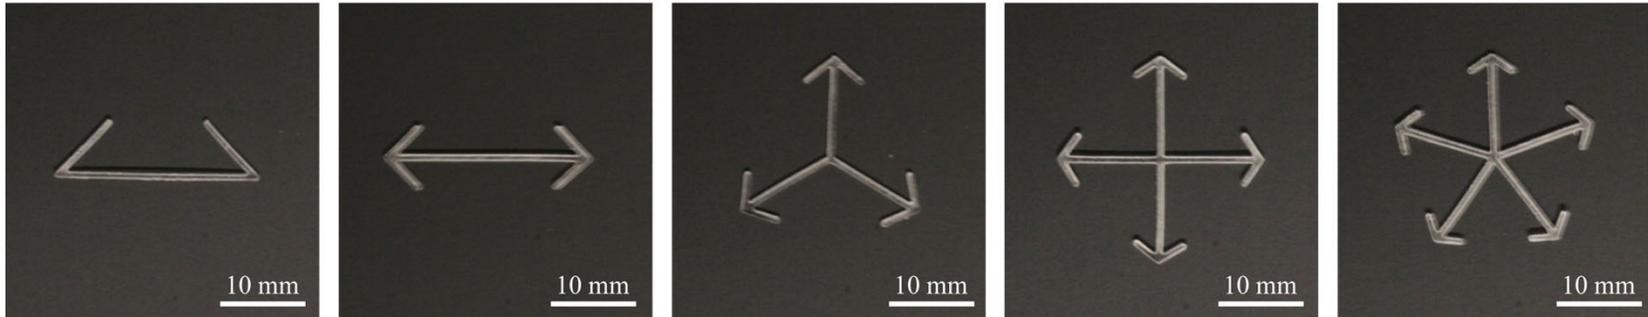

$\theta = 43^\circ$   
 $w/l = 0.43$   
 $(\phi_t)_{max} = 0.68$

Barbed particle:

$\theta = 48^\circ$   
 $w/l = 0.22$   
 $(\phi_t)_{max} = 0.93$

# Enriching particle geometry

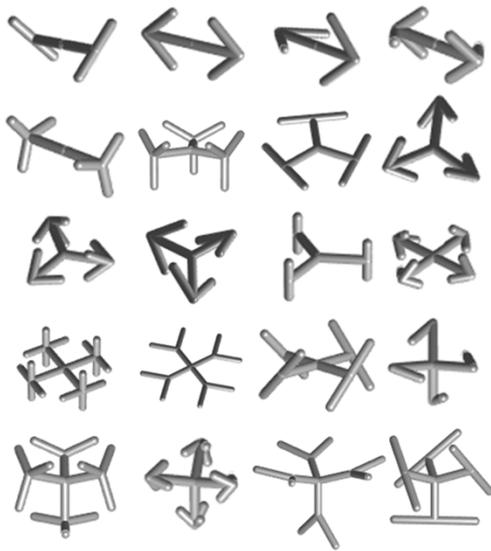

- More “isotropic” geometries
- More entanglement sites = higher entanglement densities

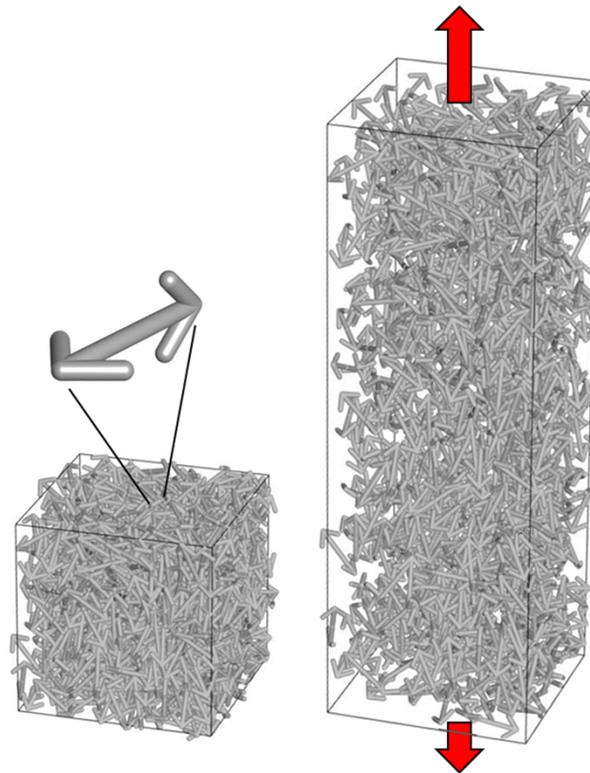

# (Many) more particle geometries

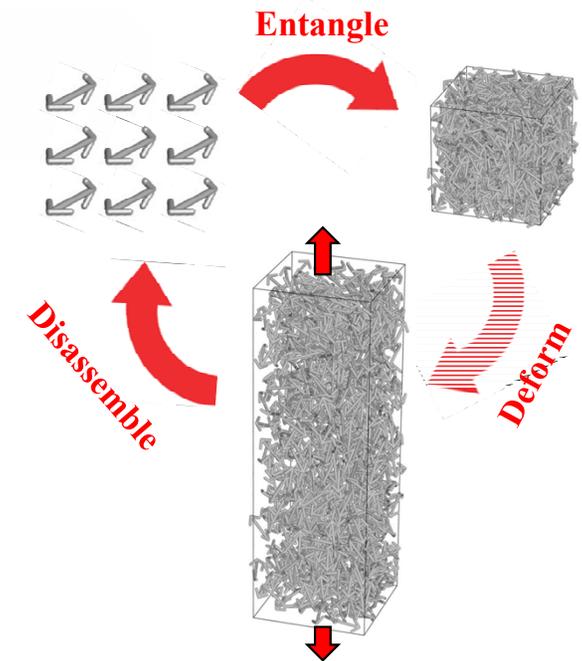

Individual particle design:  
branches, hooks and barbs

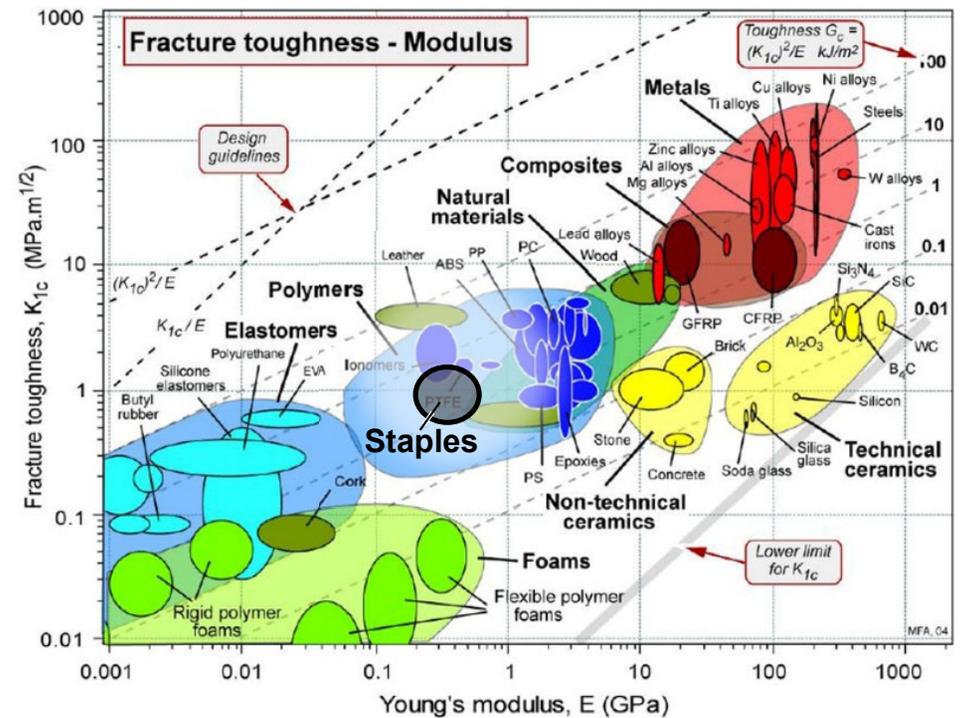

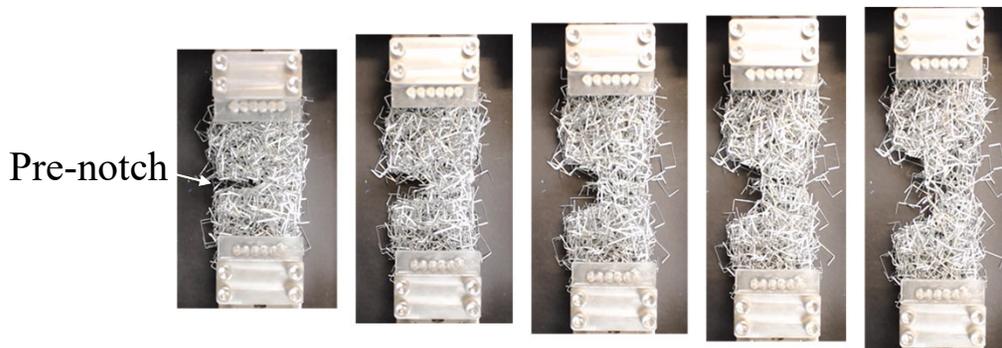

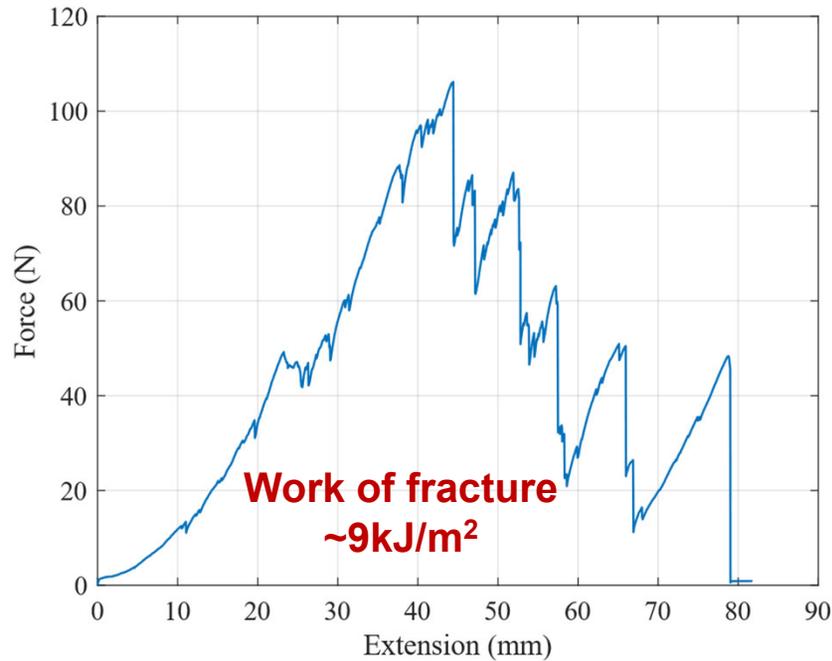

Tensile strength

Recyclability / healing

# Fracture toughness of entangled particles

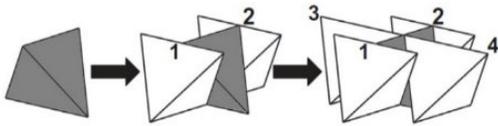

# Summary

Rigid blocks + weak and deformable interfaces + architecture

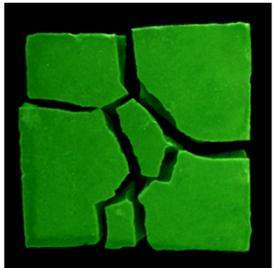

=

Rich set of tunable micromechanics and high performance

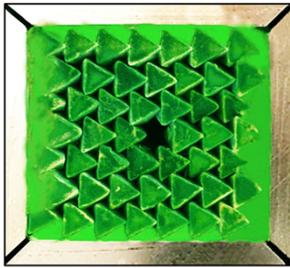

Topologically interlocked panels are as strong as the monolithic but 30-50 times tougher

Monolithic

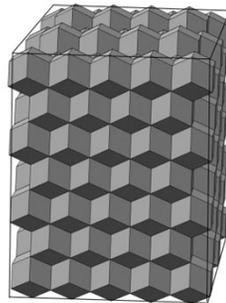

Architected

10 mm

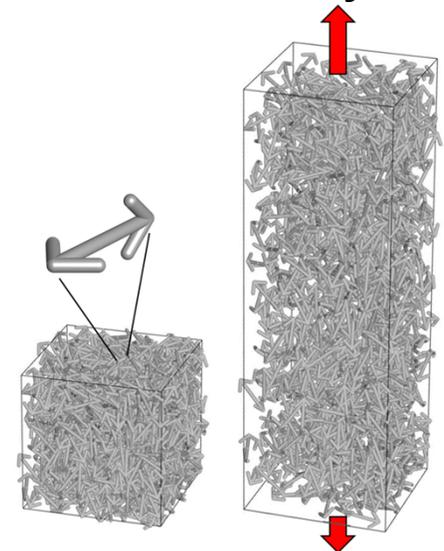

Mirkhalaf, Zhou, Barthelat  
*PNAS* (2018)

Granular crystals are 10-30 times stiffer and stronger than randomly packed spheres

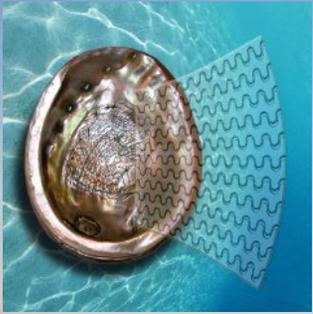

Karuriya, Barthelat *PNAS* (2023)  
Karuriya, Barthelat *JMPS* (2024)  
Karuriya, Barthelat *EML* (2024)

Entangled materials generate tensile strength, can be assembled, disassembled, recycled.

Pezeshki, Barthelat *JMPS* (2025)
